AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, &c.

Congress.—September 12th-14th, at the Way Hall, Franklin Street. Opening address at 8 p.m. on September 12th.

Murray Lands (East), at Paruna, Tuesday, September 27th. (Mr. F. E. Sumner, Secretary.)

Eyre Peninsula (Eastern), at Kimba, Monday, October 3rd. (Secretary, Mr. M. J. H. Martin.)

Eyre Peninsula (Central), at Wudinna, Wednesday, October 5th. (Secretary, Mr. Duncan Duguid.)

Eyre Peninsula (Southern), at Cummins, Friday, October 7th. (Secretary, Mr. H. M. Roberts.)

The opening session of each Conference will take place at 10.30 a.m. Papers, questions, &c., for Conferences should be forwarded to the General Secretary, Agricultural Bureau, about a fortnight before the dates mentioned above.

Congress.

The Forty-third Congress of the Agricultural Bureau will be opened by His Excellency the Governor at 8 p.m. on Monday, September 12. Addresses will be delivered the same evening by the Minister of Agriculture (Hon. S. R. Whitford) and the Chairman of the Advisory Board of Agriculture (Mr. H. N. Wicks). A Dairying Session will be held on Tuesday morning, when a veterinary lecture will be given by a Veterinary Officer of the Stock and Brands Department. This lecture will deal with mammitis, contagious abortion in cattle, and milk fever. Two more items will also be included in this session, one of which will be a paper by Mr. E. W. Mattner, of Balhannah. Simultaneously with the Dairying Session, a Fruit Session will be held in another room, when Dr. J. Davidson (Waite Research Institute) will address the meeting on "Some Economic Insect Problems of Orchard Fruits in South Australia"; a paper on "Bees: their Life History and Habits," will be read by Mr. R. Nosworthy (Balhannah); and a further paper on an horticultural subject is being arranged. On Tuesday afternoon papers will be read by Mr. A. G. Barrett on "Ideal Types of Barley for Malting Purposes"; Mr. A. L. McEwin (Advisory Board of Agriculture), "Methods of Improving Draught Stock Breeding"; and Mr. R. C. Scott, "Wheat Varieties in South Australia." In the evening at 7.45 Professor Perkins (Director of Agriculture) will give an address on "Some Points in the Handling of a Fat Lamb Flock on a Mallee Farm." The whole of Wednesday morning will be devoted to Free Parliament, when a large number of motions will be submitted to Congress. The Congress will conclude on the Wednesday evening with addresses by Mr. H. B. Barlow (Chief Dairy Instructor) and C. F. Anderson (Poultry Expert).

There will be the usual visit to the Waite Institute on Thursday morning after the Congress.

A large number of papers have been sent in for the Women's Sessions. These include "The Kitchen," to be read by a member of the Penola Branch; "Poultry Raising," Miss A. L. McKay (Penola); "Useful Knowledge," Mrs. W. J. White (Parrakie); "Hints on Making Cake Batter," Mrs. H. Altschwager (Millicent); "Bread Making on the Farm," Mrs. F. Chilman (Warramboo); "Socks and Stockings" (with demonstration), Mrs. E. L. Orchard (Belalie); "Buying a Cow," Mrs. E. M. Paddick (Kangarilla); "The Uses of Kerosene in the Home," Mrs. E. P. Wall (Eurelia); "Children," Mrs. Rita Haines (Nelshaby); and "First Aid," Miss A. M. Lawrie (Nelshaby).

Prosperity Returns

MOTOR CYCLE SPEEDWAY RACES

TREE-FELLING AND LOG CHOPPING

Are you a Member of the Society?

Members' tickets and two ladies' tickets available for the period of the show, 7 days and 7 nights, for £1 1s.

Ladies tickets are transferable and can be used by boys under the age of 14 years.

23, Waymouth Street,
Adelaide.

HAROLD J. FINNIS,
Secretary.

Following the usual practice, arrangements are expected to be made for special addresses and visits to places of interest.

All delegates of Women's and Men's Branches are requested to be present on the opening night, and to take their seats by 7.45 p.m.

Besides delegates, other members who are in town during the week are invited to attend any of the sessions.

Export of Butter.

Exports of butter from the Commonwealth for July, 1932, totalled 4,542 tons. Following is a comparison of shipments from the various States during July:—

	July, 1932.		
	United Kingdom. Boxes.	Other Countries. Boxes.	Total. Boxes.
New South Wales	9,377	4,710	**14,087**
Victoria	63,701	8,941	**72,642**
Queensland	77,902	3,722	81,624
South Australia	13,294	36	13,330
Tasmania	24	—	**24**
	164,298	**17,409**	**181,707**
	(4,107 tons)	**(435 tons)**	**(4,542 tons)**

Considering the unsettled conditions of overseas markets and the consequent intense competition, the Minister of Commerce (Mr. C. A. S. Hawker) said recently that he was pleased to observe continued improvement in our export figures, which really expressed increasing appreciation of the excellence of our products. In the present crisis the very real value to Australia of her primary industries, Mr. Hawker added, could not be too strongly urged, and he was confident that the progress achieved with dairying, as with other exports, would stimulate efforts to strengthen our position abroad still further.

Export of Eggs.

In a recent report the Minister for Commerce stated that his department had prepared a careful estimate of the probable quantity of Australian eggs which would be exported to the United Kingdom in the forthcoming season. On present indications, it is considered that between 14 and 15 million dozens will be shipped—an increase of 50 per cent. over the figures for last year. The accompanying table of exports during the last five years is a very significant index of the growth of the poultry industry in the Commonwealth:—

	Dozen.
1927	1,104,005
1928	2,916,338
1929	3,552,580
1930	5,895,090
1931	9,740,790

In addition to the quantity of eggs exported in 1931, a new development of the industry was the export of egg pulp. The quantity exported represented an additional 1,300,000 dozen eggs. A large quantity is expected to be exported this year. An idea of the extent of the market for eggs in Great Britain may be gained from the fact that in 1931 the consumption of eggs in Great Britain amounted to 549,000,000 dozen. Australia's contribution of 18 eggs in every 1,000 consumed was, therefore, less than 2 per cent. of total consumption. The per capita consumption per annum in the United Kingdom is estimated at 140 eggs.

Lawrie

Preservation of Oranges.

The Citrus Preservation Committee of the Council for Scientific and Industrial Research has recently reviewed the investigations which it has been conducting for the last four years into the best methods of handling oranges intended for storage for any great length of time. An account will be published of the committee's activities, and this account will include the conclusion which the committee has come to in regard to the various processes investigated. It is of particular interest to know that the committee do not recommend the spraying of the fruit with paraffin. A process of washing in sodium bicarbonate or borax and subsequently spraying with paraffin was one of the treatments to which the committee paid particular attention, as it has been claimed that this process, by reducing mould incidence, reduces wastage considerably.

The oranges supplied to the committee for experimental purposes were representative only of the irrigated areas of Victoria, and were sent to Melbourne loosely packed in cases. Under these conditions only a slight wastage occurred through the blue and green moulds, even in the fruit which was untreated. Evidence of the effects of treatment on wastage due to these moulds was thus inconclusive. The process was not found to lengthen the actual storage life of the fruit in any other way. It had a certain amount of beneficial effect in that it considerably improved the appearance of the fruit. All dirt was, of course, removed, resulting in the whole of it having a clean, bright appearance. In regard to the paraffin itself, a light spray can be applied without deleterious effect, but a heavy spray was found sometimes actually to cause a preventive collapse of the fruit. For this reason, there is actual danger in using paraffin with Navel oranges.

Payments of Wheat Bounty.

The Minister for Commerce stated recently that some misunderstanding had apparently arisen amongst wheatgrowers regarding an announcement in connection with payments of wheat bounty. The Wheat Bounty Act, 1931, provided for payment of the bounty of 4½d. per bushel to the grower on all wheat of the 1931-32 season sold or delivered for sale prior to October 31st, 1932. Therefore claims for bounty made by growers in respect of this season's wheat which is sold or delivered for sale before October 31st next would be dealt with by his department, and if growers desired to hold their wheat for the maximum period allowed that was their affair. Bounty would be payable on the wheat provided it was disposed of prior to October 31st, 1932. As the staff of the Wheat Bounty Sections were being reduced, however, it would be in the interests of the farmers themselves to submit their claims at an early date. If not received by the department before August 15th it would not be possible, owing to reduced staffs, to prevent some delay in payment of claims. It was to obviate such delay in the interests of farmers who had delivered wheat, but had delayed submitting claims that a previous statement had been issued giving farmers ample notice of the disbanding or reducing of the special staffs of the Wheat Bounty Section.

Australia's Dairy Produce Exports—Position in United Kingdom Market—Increase in British Imports of Butter and Bacon.

"Australia exported more butter in 1931 than ever before; in that year the value of her butter exports was 54 per cent. above the 1930 level," states the report just issued by the Empire Marketing Board on "Dairy Produce Supplies in 1931" (H.M. Stationery Office, London, 1s. net).

"Supplies of butter from Empire countries increased by no less than 30 per cent. over 1930," the report states. "Empire butter comprised almost 50 per cent. of the total imports as against 45 per cent. in 1930. Never in any previous year have Empire countries accounted for so large a proportion of the United Kingdom butter imp

TONS OF CHEESE.

Australia also had a bumper cheese season. Exports of cheese in 1931 were 2½ times the previous season's total, and the largest since 1925. The United Kingdom took 90 per cent. of Australia's butter and 93 per cent. of her total cheese exports.

Queensland, the principal shipper of butter, has increased her exports to the United Kingdom by more than 300 per cent. since 1926. Butter shipments have risen from 9,400 tons to 30,000 tons. Total shipments from Australia have risen during the same period from 28,000 tons to 66,000 tons.

WORLD'S LARGEST IMPORTER.

Britain now imports more butter (by value) than any other single commodity. In 1931 she paid more for her imported bacon than for her imported wheat. These are two of the facts brought out in the report, which states that the United Kingdom is the world's largest importer of dairy produce. Fully 30 per cent. of her total imports of food, drink, and tobacco are accounted for by dairy produce. Her imports of butter alone were worth £46,358,000 in 1931—nearly double the amount imported before the war.

The total value of Britain's imports of dairy produce of all kinds, including eggs, bacon, poultry, and pork, has risen from £67,262,000 (the average of the three years before the war) to £126,002,000 in 1931, when new records were established for the imports of butter, bacon, poultry, cream, and certain types of preserved milk.

Denmark held her position in 1931 as the chief supplier of butter, and sent Britain 31 per cent. of her total imports. New Zealand came next with 24 per cent., and Australia accounted for 19 per cent. of Britain's total imported supplies. Other Empire countries which increased their exports of butter to the United Kingdom were South Africa and Kenya. Russia increased its supplies by 2½ times, and jumped from eighth to fourth place. The volume of Russian imports, however, was still well below pre-war level.

EATING MORE EGGS.

Over 3,100,000,000 eggs were imported into Britain last year. The volume of Empire supplies was the largest ever recorded, and accounted for 24 per cent. of the total imports. Denmark is the chief source of imports, sending 29 per cent. of the total from all sources. Britain draws her imports of eggs from, altogether, over 30 countries.

The Empire supplies fully 87 per cent. of Britain's total imports of cheese, New Zealand and Canada being the chief sources. A seasonal difference in price between white and colored cheese is a feature of the cheese trade. From February to October colored cheese appeared to be most in demand, but from November to January white cheese became dearer than colored.

AUSTRALIAN FROZEN PORK.

Supplies of bacon to the United Kingdom were, states the report, "on an unprecedented scale" in 1931. Imports rose by 1,950,000cwts. or 21 per cent. compared with 1930, which was in itself a record year. Britain is importing considerably over twice as much bacon as in the years before the war. This figure has arisen from 4,787,000cwts. to 11,138,000cwts., valued in 1931 at £33,136,000. Empire supplies represented only a small part—3 per cent.—of the total imports.

The Empire is, however, supplying most of Britain's frozen pork. "One of the most striking features of the supply position is the increase in shipments from Australia, which were practically negligible before 1930. The quantity imported from Australia in 1931 was nearly four times as great as in 1930." Empire supplies, as a whole, accounted for 59 per cent. of the total imports of frozen pork in 1931. The United States is the chief foreign source of supply.

Lawrn.

POSITION IN GERMANY.

The report also surveys briefly the position of the dairy produce market in Germany, the world's most important market for butter next to the United Kingdom. In 1931, imports of Australian butter into Germany rose to 30,000cwts. from under 400cwts. in 1930. Germany's total imports declined considerably, however, owing to tariff restrictions and diminished purchasing power. Consumption of butter fell by 5 per cent., whereas, in the United Kingdom, it rose by 14 per cent. Germany also ranks second to the United Kingdom as an importer of eggs. Imports of eggs declined by 12 per cent. in 1931.

Poisoning Blowflies.

Replying to a question submitted at the Ceduna Conference as to whether arsenical sheep dips would be strong enough to poison blowflies, Mr. A. H. Robin (Veterinary Officer, Stock and Brands Department) stated that arsenical preparations were most satisfactory for poisoning blowflies, and if sheep were dipped in arsenical sheep dip mixed at ordinary dipping strength, the treatment would not only serve to kill any maggots that may happen to be in the fleece at the time of dipping, but it would further protect the sheep from "fly-strike" for a period of three or four weeks. This was due to the fact that when the dip was being prepared, all of the arsenic was not immediately dissolved in the water, but some of it remained "in suspension," and in the process of dipping was deposited in the fleeces of the sheep in fine, solid particles. There it was gradually dissolved out by moisture in the fleece, thus keeping the wool impregnated with arsenical solution sufficiently strong to poison flies that might light on the sheep and any maggots that hatched out from eggs deposited in the fleece.

The period of protection afforded the sheep could be considerably lengthened by using the arsenical dip mixture in greater concentrations. It was, of course, not safe to immerse the sheep completely in these stronger solutions, and the application of them was therefore restricted to the "breech," which was the part of the animal most susceptible to fly attack. Two methods of application were commonly employed, viz.:—

(1) *Jetting.*—This consisted of the application, around the breech of the sheep, of arsenical dip mixed at a strength of four times that recommended by the manufacturer for ordinary dipping. This solution was applied by means of a special high pressure pump with a very fine nozzle. It was claimed by those who used it that this method of treatment would afford the sheep 90 per cent. to 95 per cent. effective protection up to three months, depending on weather conditions, and it further did away with the necessity for crutching. Owing, however, to the high cost of the special jetting apparatus, the use of this method of treating the sheep was generally confined to large runs.

Swabbing.—Arsenical dip solution mixed double ordinary dipping strength was used, and was applied to the breech area by means of a small rag mop on the end of a stick. The solution might be poured on the sheep and spread with the mop, or the mop might be dipped into a tin containing the preparation and then thoroughly rubbed over the area. This method of treatment was suitable for small farmers' flocks.

Forage Poisoning.

At the Ceduna Conference Mr. A. H. Robin, B.V.Sc., explained the best method of feeding hay that had been badly damaged by mice. It was extremely likely, he said, that as the result of the ravages of the mice the fodder in the stacks would have become musty or mouldy, in parts at least, and that further it might have become impregnated with the deadly *Botulinus* toxin or poison, the ingestion of which gave rise to the very fatal disease of stock, commonly known as "forage poisoning." Horses in particular were very susceptible to this disease. Sheep and cattle were also susceptible, though considerably less so. It would be necessary, therefore, for stockowners, when utilising this damaged fodder, to take certain precautions to safeguard the health of their stock. It should all be carefully inspected and any affected hay with must or mould should be discarded. Those sheaves that appeared to be clean and fit for use should be well shaken to free them from dust, and then opened up so as to expose their contents thoroughly to the air and sunlight for 48 hours prior to feeding. This exposure would serve to oxidise and destroy any possible *Botulinus* toxin on the fodder, to the extent of rendering it reasonably safe to use. With respect to actual methods of feeding it to the stock, any of it that was suitable could, if desired, be fed as hay. On the whole, probably the most suitable way of utilising it would be to chaff it, and either mix it with other sound feed, or, if this was not possible, damp it with molasses and water to improve its feeding value. Because of the lesser susceptibility of cattle and sheep to forage poisoning, it would be preferable to use it up by feeding it as far as possible to those stock rather than to horses.

Purifying Water Polluted by Dead Mice.

For purifying water, polluted by dead mice, the Acting Director of Chemistry recently suggested that the water should be sterilised by stirring into every 100galls. of water 2½ozs. of bleaching powder, and, after a quarter of an hour or longer, stirring in some liquid ammonia, say, half a teaspoonful at a time, until there was no smell of the bleaching powder left. He, however, recommended that before the water in the tank was treated a certain quantity should be taken from the tank and treated in the proportions stated. Should the treatment result in the water being fairly free from offensive smell and taste, he considered it would be safe to use it after it had been boiled, and the balance in the tank must then be treated likewise. If the water did not respond to the treatment, it was considered that it would be contaminated to the extent that it would not be fit for use. He would be pleased to be informed by anyone using this method as to the result of the treatment.

Preserving Super Bags.

In discussing at the Ceduna Conference the method that might be adopted to preserve super bags when emptied, the General Secretary stated that a fertiliser manufacturing company had recommended the use of one teaspoonful of bicarbonate of soda to every 2galls. of water, soak well, and finally rinse the bags in clean water. A delegate said that he had obtained good results by soaking the bags in sea water. Mr. S. Shepherd (Advisory Board of Agriculture) informed the Conference that he had used bags four times and thus saved 5s. 6d. a ton in his purchases of super. His practice was to empty the sheep dip and flood it with water. He then filled the dip with the bags and left them for two or three weeks, and he found that when removed they were in good condition.

Pasture Competitions.

The South Australian Advisory Dairy Board is arranging for pasture competitions in three districts of the State, namely, Central, South-Eastern, and Irrigated Areas. Entries are due not later than Wednesday, August 31st, 1932, and will be restricted to dairymen milking at least seven cows. Prizes consisting of trophies to the value of £3 3s., £2 2s., and £1 1s., together with Certificates, are offered for each district. A fee of 1s. will be charged for each entry.

Entries are to be for pastures of not less than 5 acres for Central and South-Eastern districts, and 3 acres for Irrigated Areas. Competitors will be asked to state clearly in their applications:—(*a*) The location of pastures; (*b*) the area of these pastures.

It is hoped that dairymen will support these competitions, and information will be readily supplied to applicants by the Hon. Secretary, South Australian Advisory Board, office of Minister of Agriculture, Adelaide, to whom entries should be forwarded.

Export of Barley.

The Minister for Commerce (Mr. C. A. S. Hawker) reports that the figures for the export of barley from Australia for the 11 months ended May, 1932, disclosed a considerable increase over the figures for 1931, as follows:—

1931 (11 months) .. .. 1,522,293 centals, valued at £368,120
1932 (11 months) .. .. 1,588,473 centals, valued at £431,404

According to advice received, about 46 per cent. of Great Britain's imports of barley were used in brewing, and somewhat over 50 per cent. for all malting purposes, the principal countries of origin being California 60 per cent., Chili 7 per cent., Czecho-Slovakia 5 per cent. Of the 599,313 tons of barley imported into Great Britain in 1929, Australia's share was about 1½ per cent.

Provided that the production of suitable types of good quality barley was maintained, and the volume expanded, there appeared to be a reasonable prospect that Australia could secure a greater share of the English market. Considerable attention has been paid to the production of barley in South Australia and Tasmania, and further success would no doubt ensue with a closer knowledge of the types in favor on the English market.

Trade with the East.

The latest statistical information published by the Minister for Commerce concerning Australia's trade with the East shows that in the principal commodities, with the exception of frozen meat, there has been an increase when compared with the previous year. This is highly gratifying when it is remembered that 1930-31 was a record year in so far as the volume of trade was concerned. The comparative statement of the principal exports during the first nine months of 1930-31 and 1931-32 shows the following:—

	Nine Months, 1930-31.		Nine Months, 1931-32.	
	Centals.	Value. £	Centals.	Value. £
Butter	79,858	460,908	95,063	502,452
Flour	2,377,105	899,216	3,184,389	1,010,164
Wheat	17,840,305	3,845,893	24,295,341	5,823,688
Wool	1,067,703	4,337,709	1,513,769	6,192,658
Beef	100,829	182,116	65,634	128,728
Mutton and lamb .	16,384	36,280	15,269	29,849

The exports of other commodities of primary production for the first six months of 1931-32 to the East were:—Milk and cream, 51,475 centals, £253,000; canned fruits, 3,417 centals, £6,499; cheese, 1,267 centals, £5,903; sheep, 12,268, £4,012; wine, 1,418galls., £547. The requests for information relating to trade have covered an exceptionally wide range of commodities. Primary products, other than those mentioned above, in regard to which inquiries were made include the following:—Dried and fresh fruits, dairy cattle, flour, fodders, feed oats, hides, and skins.

Standardisation of Export Apple Cases.

The Standards Association of Australia has been asked to carry out work on the standardisation of export fruit cases, and has referred the matter to a special committee, of which Mr. I. H. Boas, Chief of the Division of Forest Products, Council for Scientific and Industrial Research, is chairman. The committee decided to restrict its work in the first instance to apple cases. Evidence is abundant that the use of a number of different types of case causes serious inconvenience in shipping, and consequently adds to the cost. Furthermore, there is a great conflict of opinion as to the relative merits of the local hardwood dump case and the imported softwood standard case in their ability to carry fruit to London in the best possible condition. The committee was faced with this conflict based upon more or less general observations, and asked the Division of Forest Products to carry out a series of experiments to definitely establish the facts. This work was begun in May of this year by the Senior Plant Pathologist of the Division of Plant Industry, and the Utilisation Officer of the Division of Forest Products.

It was found advisable to restrict the work in the present season to the development of a suitable technique. The main idea was to develop tests which would yield results translatable into actual practice. After two months' work, involving the careful packing, testing, and re-examination of over 70 cases of apples, a good basis has now been laid for a far more extensive series of tests in the next season. The extent of the work involved can be seen from the fact that this year the detailed examination of over 7,000 apples was carried out. The details of all bruising were recorded and analysed. Some very important facts were indicated, but it will not be reported until further work on a larger scale confirms them. It is expected that established facts will then replace the present opinions, and definite steps on standardisation will follow.

Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of the following publications:—

"Intensive Systems of Apple Production." Bulletin 49, Ministry of Agriculture, England. Price, 9d. net.

"Dairy Produce Supplies in 1931." Empire Marketing Board. 1s. net.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Agricultural Bureau, Hindmarsh Island, reports—(1) Cow just calved but no milk supply, and (2) ewes with sore lips.

Replies—(1) Failure to secrete milk may be due to atrophy and wasting of the substance of the udder as the result of former disease of the gland, or it may be merely a temporary functional disorder of the milk secreting cells. If the udder seems healthy and [illegible] faulty apparently in size and activity, it should be massaged two or three [illegible] with a little olive oil, and "stripping" of the teats should also be practised. A [illegible]ative medicine can be given, and the animal's diet changed to sloppy, nourish[illegible] Warm milk may also be given to drink if the animal will take it. One (1) tea[illegible]ul of powdered nux vomica should also be given on back of tongue 3 times daily fo[illegible] few days. (2) The trouble is probably a necrotic stomatitis. Change the ewes on to fresh pasture. Scrape or soak off all scabs, and after drying gently smear lightly with 5 per cent. carbolised vaseline ointment. If the sores extend to the inside of the lips and on the gums, bathe these gently with weak Condy's solution and then daub with weak tinct. iodine (tinct. iodine, 1 part; water, 2 parts). Two or [illegible]ee daily dressings should be all that is necessary to effect a cure.

Agricultural Bureau, Wasleys, reports cow showing shortage of milk. Milk from teats is curdled.

Reply—The condition is Mammitis. The following treatment is advised:—(1) Isolate cow. After treatment disinfect hands before milking other cows. (2) Apply hot packs 3 to 4 times daily to affected quarters. (3) Subsequently dry and massage gently with warm camphorated oil. (4) Strip out affected quarters 6 to 7 times daily. Affected milk should not be stripped on to floors or yards. Owing to the nature of this disease, vaccination is not as satisfactory either as a curative or a preventive for mammitis as it is for some other disease. The Commonwealth Serum Laboratories have a mixed mammitis vaccine which could be tried, either to prevent the disease or to treat cases of mammitis. The price per cow (to prevent disease) is 3s. 6d. Should you consider trying the vaccine on your herd I would advise you to pay a personal visit to this office and discuss the matter.

Weavers Agricultural Bureau reports—(1) Cow with badly cut teat partly healed, but milk is leaking; (2) heifer with very large navel.

Replies—(1) Nothing can be done until the cow is dried off. It will then be necessary to scarify the edges of the wound with a clean sharp knife so as to leave a fresh healing surface. If possible a deep stitch of silk soaked in iodine should then be inserted to bring the edges close together. This stitch should be removed in seven days' time. (2) If the swelling in the region of the navel has not decreased in size by the time the calf is 10 to 12 months' old, it should be sold for slaughter.

Clanfield Agricultural Bureau asks for dressing to reduce swellings caused by bruised shoulders on horses.

Reply—The bruising under such conditions is due to horse being "out of condition." Such cases should be put out of work or else a breast collar used. The following dressing is suggested:—Lead acetate, 1oz.; zinc sulphate, 6 drams; water, 1 pint. Apply lotion 3 or 4 times daily.

Warramboo Agricultural Bureau reports mare with foal—mare's udder is very sore, hard, and swollen.

Reply—It is possible that the mare has a chronic mammitis (inflammation of the udder). Do not allow the foal to suckle. Apply hot fomentations 2 or 3 times daily for a few days. If any abscess formation takes place lance swelling with a clean, sharp knife and syringe out with lysol solution. If condition does not clear up, it is not advisable to breed from mare, because udder cannot then function properly.

Brentwood Agricultural Bureau asks—(1) Are horses more subject to forage poisoning than cattle or sheep; (2) is danger lessened by exposing fodder to air; (3) what is the cause of the poisoning; (4) horse very sluggish, heavy cough, and labored breathing; (5) mare with severe constipation.

Replies—(1) Horses are much more susceptible than cattle or sheep, though the latter can also contract this disease. (2) If the affected fodder is well opened up and exposed to air and sunlight for 48 hours prior to feeding, this exposure will help to oxidise and destroy any poison on the feed, and render it reasonably safe for use. (3) Contamination by the toxin or poison produced by the *Bacillus botulinus* when growing actively on the fodder. (4) The animal is apparently broken winded. Treatment for this trouble can only be palliative. So far as possible, bulky feeding should be avoided, the feeds being made nutritious and concentrated. The feed should be given lightly damped to prevent any dust in it causing irritation to the throat with resultant coughing. The animal should further never be put to work within an hour or so after feeding. An occasional drench of raw linseed oil, 1½ pints; turps, 4 tablespoonsful; can be given to maintain the bowels in good order, and one tablespoonful of Fowler's solution of arsenic can with advantage also be given in the feed night and morning for a fortnight. (5) In cases of bowel stoppage, the purgative drenches and enemas should be supported by giving night and morning 1 level teaspoonful of powdered nux vomica. This is best given by mixing the dose in a spoonful of honey or treacle to make a paste, which can be smeared on the animal's back and tongue.

1/

Agricultural Bureau, Myponga, asks what signs indicate a sow being on heat.

Reply—The usual signs are that the sow exhibits restlessness and utters peculiar cries or grunts. The sexual organs become enlarged and the vulva protrudes and is inflamed and swollen. In many cases she attracts attention by repeatedly jumping on the backs of other sows.

"Spalding" reports death of horse. Symptoms:—Fed on good feed; in great pain, passing water frequently whilst being dosed, struggled and died very suddenly.

Reply—The horse apparently died from a severe attack of flatulent colic. Care is necessary in putting horses and all stock on to such young green feed. Horses frequently get serious forms of colic, and laminitis is also common. The treatment suggested for a draught horse is:—(1) Give this drench at once: Raw linseed oil, 1½ pints; oil of turpentine, 2ozs.; household cloudy ammonia, ½oz. (2) Give enemas of warm, soapy water (3 to 4 gallons) every 3 or 4 hours if necessary.

Agricultural Bureau, Elbow Hill, asks cure for blood worms in horses.

Reply—(1) Starve horse for 24 hours. (2) At end of that time give the following drench:—Raw linseed oil, 1½ pints; oil of turpentine, 4 tablespoonsful. (3) Subsequently give one tablespoonful of Fowler's solution of arsenic in a small damped feed night and morning for 14 days (buy a 1lb. bottle of the solution). (4) Feed regularly on good quality chaff, bran, and crushed oats. Good management and good regular feeding by keeping the horses in good condition lessens greatly the effects of worm invasion.

Ceduna Conference: What is the best ration to prepare a draught stallion for the breeding season?

Reply—It is not possible to set out any specific best ration for this purpose as so much depends on the individuality of the animal, whether it is an easy animal to get into condition, or whether it is a hard one. There is no necessity to use any special nostrums in the way of feeding, such as eggs, condiments, &c., the job can be done quite satisfactorily with the ordinary farm foods. As a basis to start operations I would suggest that the animal be fed four times daily at regular intervals, each feed to consist of ¾-1 kerosene tinful of chaff, 1lb. bran, ¾lb. crushed oats. In addition, a moderate allowance of green feed can be given daily and ½lb. boiled whole linseed twice weekly. A lump of rock salt should be kept in the manger, and, of course, water supplied, *ad lib*, to drink. As one goes along it may be found necessary to vary this ration somewhat—a little more or less feed may be required, or the grain allowance may have to be increased or decreased, &c. But these are all matters of detail that have just got to be left to the judgment of the owner. The aim must be to get the animal into good flesh and not have him hog fat and soft. His feeding must therefore be worked out in conjunction with the provision of plenty of regular exercise that will make for that necessary "hardness," and for this purpose there is nothing better than to put him to some regular, honest work about the farm. Failing this, he ought to be given at least four or five miles of steady road work daily.

FEDERATION WHEAT AND RUST.

A correspondent at Cowell has been advised by the Supervisor of Experimental Work (Mr. R. C. Scott) that Federation wheat is very susceptible to red rust, but the severity of the disease depends entirely upon the character of the weather in spring or early summer. Varieties which mature early frequently escape, because they have reached a sufficient stage of maturity before rust-favorable weather is experienced. Therefore, if Federation is sown early in the season it has a greater chance of escaping than if sown late. At the same time, should humid climatic conditions obtain before the grain has become firm, Federation may be badly attacked by red rust, notwithstanding early planting.

TWO REASONS

why YOU should order

"WATTLE" BINDER TWINE

The First and Chief Reason is the "WATTLE" Brand deserves your confidence.

It is manufactured in a modern factory from highest-grade materials. It is unusually strong, even, clean, and cuts out harvest-time delays caused by binder twine breaking and fraying.

"MADE IN SOUTH AUSTRALIA"

is the Second Reason—you give your State a "helping hand" toward prosperity every time you buy "WATTLE" Brand—and incidentally do yourself a good turn at the same time.

"A GOOD TWINE SAVES TIME."

"WATTLE" BINDER TWINE

Obtainable in Three Grades

BLUE CROSS

HOLDFAST SPECIAL

WATTLE SUPERIOR MANILA

'PHONE L. 5137

Manufactured by

ADELAIDE ROPE & NAIL CO.
LIMITED,
CROYDON, SOUTH AUSTRALIA.

SUPPLIES OBTAINABLE FROM ALL DISTRIBUTORS

VARIETAL PURITY AND STABILITY IN WHEAT, OATS, AND BARLEY.*

[By Allan R. Callaghan, D.Phil., B.Sc. (Oxon), B.Sc. Agr. (Syd.).
(Principal, Roseworthy Agricultural College.).]

INTRODUCTION.

Few questions are of greater agronomic interest, or present such fundamental and intricate problems as those concerned with the conception of a variety as an agricultural unit. To the majority of those dealing with varieties of farm crops in the course of every day life, the variety is a simple and understandable item in their industry; it will probably surprise them, therefore, to know that concealed in each variety are some of the most subtle and evasive of the scientist's problems.

Occasionally impurities are noted in varieties far in excess of the average, their very presence leads to alarm which more often than not spreads beyond the bounds of the farm concerned; inexplicable theories are usually advanced by way of explanation, and by inaccurate interpretations of its behavior the variety is very often seriously libelled. It is in reality a case of misrepresentation leading to misinterpretation. Indeed, the nature of the variety as such is pathetically misunderstood; it is blamed for "reversion," "running back to the wild form," "splitting up," "running out," and in fact "not being what it used to be." Another expression, "reversion to type," is equally baffling; a term which, on analysis, from the point of view of the variety, adds insult to injury. With full and appreciative respect for the work performed by practical agriculturists, the plant breeder is unable to accept such expressions. Whilst they probably possess the virtue of being impressive, as an explanation, they are meaningless, and obviously vague.

The plant breeder is concerned with the evolution of new varieties, and also with the maintenance of the structure of already existing sorts. He is also interested in the preliminary trial and behaviour of all varieties under field conditions, for without this intimate contact the practical utility of his work would diminish in direct proportion to his lack of interest; besides this the faith and hope in his task, which are his chief inspirations, would be gradually lost. New varieties leave his hands to face the crucial test of field trials and commercial farming, consequently he is interested in their subsequent behaviour and all criticism or commendation pertaining thereto.

Seldom are farmers fully acquainted with the process of fixing a new variety, and whilst the agronomic worth of any variety may be, and is eventually in all cases, correctly interpreted by them, the variety as such is often misunderstood. The question of varietal behaviour is so constantly with all agriculturists, from the plant breeder, through the field officer to the farmer, that its general elucidation as far as that is possible should be welcome. This involves an understanding of a few of the basic principles of breeding, and an attempt is made herein to express lucidly, if briefly, those which govern varietal purity and stability. The objects of this article are therefore threefold, (1) to portray as clearly as possible the intricacies concerned in the problem of seed-purity and varietal stability, (2) to define the principles which form the foundation of the pure-seed production of any variety, and (3) to correct some misconceptions and misinterpretations of certain irregularities which are often alleged to be features of established varieties.

---

*Numerous articles bearing upon this subject have appeared in the various agricultural and scientific journals of the world. This article is written for a general purpose and in a general manner, consequently no explicit references to literature have been cited. Most text books on Genetics deal in detail with the scientific principles involved herein.

THE APPLICATION OF THE PURE-LINE THEORY.

Many old ideas still retained with regard to varietal phenomena are based on the foundational works of Charles Darwin. If one were to read the "Origin of Species" and neglect the discoveries and developments made since then, it would be possible to formulate many of the ideas which unfortunately are still in currency. It is amazing the number who still believe that constant selection within a self-fertilised variety will continuously transform the variety in favor of the lines of selection. Many arguments might be raised in favor of such opinions, based mainly on the success of early selectionists, but none remains valid in the light of the pure-line theory advanced by Johannsen in 1903 and confirmed by the genetical knowledge which has accumulated in the last 20 years.

This theory has a Mendelian explanation, and it is based on the fact that if an individual plant of a self-fertilised line is homogeneous for the factors determining all its characters, then its offspring will breed true in all details; further, selection within such a pure-line cannot possibly modify any particular character or characters in the subsequent progeny. It has, however, certain limitations in general practice for it pre-supposes absolute self-fertilisation in the first place, and in the second place, homozygosity (absolute purity) of all characters. It asserts that having once obtained homozygosity of any variety, that is a pure-line, and provided self-fertilisation continues in future generations, such a variety will, in the normal course of events, remain pure, and selection within it is absolutely without effect. In other words, it would remain identically the same from one generation to another; it would be neither capable of degeneration nor improvement.

From this then the queries arise: Are our varieties pure-lines in the truest sense of the word? If not, what degree of relative purity do they possess? The heritable characters of the plant are inseparably associated with any answers that might be given to these questions. These characters fall into two major categories —(*a*) morphological characters, most of which are definite and readily defined; and (*b*) physiological characters, most of which are masked from observation, and difficult of definition.

On the basis of our present knowledge it is considered that all characters are inherited according to Mendelian principles, that is, each character has a factor or set of factors determining its expression which is independently inherited. The more obvious morphological characters of wheat, such as color of grain, color of glumes (chaff), degree of beardedness, and so on, are easily traced, and their inheritance can be followed. It is more difficult to follow morphological characters of a qualitative nature, such as strength of straw, shedding characteristics, or flour strength, because the character itself evades exact description and is affected by local environment. It is even more difficult, and in some cases impossible, to trace the hereditary traits of most physiological characters for the reason that they are hidden and only find expression in the general life and prolificacy of the plant.

It will be seen, therefore, that although a variety may be produced true to a certain morphological description there is no proof that it is also true for the invisible and more abstruse physiological characters. It is, however, permissible to assume that a variety breeding true for its outward and visible characters will also, as a general rule, according to Mendelian principles, react with very reasonable consistency from the physiological viewpoint, that is, in vigor, disease reaction, and yielding capacity. Having fixed a group of factors, the characters which these factors determine will breed true, and in the strictest sense of the word, such a variety is a pure-line as far as the particular characters in question are concerned, and it will breed true for them whilst ever self-fertilisation continues uninterrupted. This, then, must serve as the interpretation of the degree of purity it is legitimate to apply to our own varieties of wheat, oats, and barley. Whilst it is correct to say that they are pure-lines for all characters with which the agriculturalist is concerned, theoretical data limit their acceptance as pure-lines accordingly.

The process of fixing a type will be dealt with subsequently, but before going into the details involved therein, much unnecessary discussion on the relative fixity of types may be avoided by arriving at the true agricultural conception of what may constitute a variety.

THE VARIETY CONCEPT.

The conception of a variety of any crop, and of cereal crops in particular, is a purity concept, and as such, varietal identity in the minds of all agriculturalists from the plant breeder to the farmer should be governed by this conception. It is, however, very often at fault; from the foregoing it is clear that many fallacies arise as the result of the retention of old ideas which have been left unceremoniously behind in the progress of biological learning, other fallacies arise through lack of knowledge of basic principles.

Technically speaking, a variety should be defined as a pure-line, but it is impossible to be certain that all the plants belonging to the one variety are identical in all physiological and morphological factors. The variety as used in agriculture is a unit with which the grower is so vitally concerned that a truer definition should be attained by approaching the matter from the viewpoint of the farmer.

The first thing demanded of a variety is a capacity to yield well; unless it is prolific and capable of yielding as well as, or better than, any other variety under similar conditions of culture, the farmer is not interested. Unconsciously, he thus stresses the importance of physiological characters. This is as it should be, for after all, the true measurement of the general physiology of any variety is its production; conversely the yielding capacity of any variety is the agricultural expression of its physiology. First and foremost, then, a variety must be able to retain its yielding ability under conditions of a given environment which implies the possession of a certain physiological stability, or in other words, it must be fixed for those attributes that combine to make it yield well. It does not necessarily follow that such a variety is fixed for every physiological character, but, as will be shown later, after several generations it may contain different physiological strains, all of which may yield up to the standard required of the variety as a whole, but which may react differently under different environmental conditions or to different diseases.

Unfortunately, only very few physiological factors of a variety find morphological expression, of these the most accessible to study are disease reaction and maturity; consequently it is possible to fix a type, in a comparatively short time, which will be resistant to a certain disease, or form of the disease, and which will mature evenly. Yield, being of paramount importance, is given special attention, and by selecting and retaining these strains (of any crossbred) of high yielding ability, the combination of the most desirable physiological characters is obtained and fixed unconsciously.

It will be seen, therefore, that from the physiological standpoint at least, there is an allowable agricultural interpretation of the word "variety," which in itself implies a certain latitude or departure from the scientific definition of a pure-line. The morphological aspects of the problem invariably receive greater attention and emphasis, because they represent the variety as recorded by the senses. The desire for uniformity in visible characters is based chiefly on the assumption that if a variety is not breeding true for morphological characters it cannot be expected to be true for the important factors governing prolificacy. Consequently, every endeavor is made to obtain cultural races which will breed true to a certain taxonomic description. Even from this aspect of the problem there is an agricultural allowance, for many minute morphological details are overlooked, and varieties may be distributed which if submitted to detailed scrutiny would reveal certain inherent differences. It is a just conclusion, therefore, that although the plants constituting a variety may differ inherently from one another in minute details, they are inherently similar in all the obvious characters which enable them to be distinguished as a group from any other group of plants fixed for a similar set of characters. The agricultural variety, or *race culturale*, therefore, is conceived in the first place as a morphological unit, but its subsequent importance agronomically depends upon its physiological characters which determine its capacity to yield well in comparison with other varieties. Both morphological and physiological aspects demand a certain degree of purity, to carry the demand to absolute purity is unwarranted, and the agricultural conception whilst directed to absolute purity is fulfilled by a standard of relative purity. Provided the plants representing a variety are sufficiently homogeneous to constitute a group which has inherent morphological and physiological characters which make it distinct from any other such group, minor inherent differences between the plants within the variety are permissible.

Having fixed a variety according to this conception it is released for general culture; it is a pure-line as far as its most important characters are concerned, this defines it as a separate type, and no departure from this type is to be expected, and its standard of purity may be expected to remain uniform.

FIXING THE TYPE.

A variety on leaving the plant breeder is spoken of as a "pure-line" according to the concept outlined above; in all visible and measurable characters, and to all intents and purposes it is breeding true. The production of such a pure-breeding line involves a general principle which is best explained by adopting symbols rather than genetical terms. Briefly stated, this principle implies that where continued self-fertilisation (as in wheat, oats, and barley) is allowed to proceed without selection, the resultant plant population, after a few generations, will approach complete homozygosity, or in other words, consist of a number of pure-lines. This principle is governed by the Mendelian laws of inheritance, and the theoretical summary cited below illustrates the operation of the process for one pair of allelomorphic (opposite) factors, assuming that these factors are inherited as simple Mendelian units segregating in the ratio of 1 : 2 : 1.

Take *A* to represent one character (say brown chaff) and *a* to represent the opposite character (in this case white chaff). Assume now that a wheat (*AA*) pure for *A* is crossed with a wheat (*aa*) pure for *a*; the plant or plants so obtained would be heterozygous and represented as *Aa*, that is, they would possess both characters *A* and *a*. The progeny from these plants, according to the laws of inheritance, will segregate or, in other words, combine to produce types *AA*, *Aa*, and *aa* in the ratio of 1 : 2 : 1. In this generation it will be seen the percentage of heterozygous plants (*Aa*) is just 50 per cent. of the total population. Now *AA* and *aa* represent a pure or homozygous condition, and will breed [illegible] accordingly; only the 50 per cent. of *Aa* will continue to segregate. It is evident, therefore, that in each succeeding generation the percentage of *Aa* types will rapidly decrease.* The progeny from the 1 *AA* : 2*Aa* : 1*aa* population will be in the ratio of 3*AA* : 2*Aa* : 3*aa*, and in this the *Aa* plants only represent 25 per cent. Continue the in-breeding, and in the next generation the ratio becomes 7*AA* : 2*Aa* : 7*aa*, in which *Aa* plants only represent 12.5 per cent.; in the following generation it becomes 15*AA* : 2*Aa* : 15*aa*; in the next it becomes 31*AA* : 2*Aa* : 31*aa*; whilst the offspring of the latter would be in the ratio of 63*AA* : 2*Aa* : 63*aa*, in which the *Aa* types form less than 1 per cent. of the total number of plants.

It is apparent that before very long the percentage of *Aa* plants would be so small as to be negligible, and the population would consist almost entirely of *AA* (brown chaff) and *aa* (white chaff) plants. In other words, the population would have reached a state of almost complete homozygosity. It would then be possible to select plants from the population which would breed true for the character in question, that is, either white or brown chaff. As the principle holds good for all characters, however, it is possible to speak more generally, and say that selections could be obtained from such a population which would breed true to the type selected.

In effect the plant breeder is guided by such knowledge, but he hastens fixation (the homozygous condition) by selecting individual plants, which conform to the type he is seeking, from every generation until such time as no noticeable variation exists in the progeny. Until this latter condition is reached it is in his interests that the seed of the whole population should not be bulked, otherwise it would ultimately stabilise itself as a number of pure-lines by means of the process referred to above.

It is very clear, therefore, that the judgment and care of the plant breeder has a deciding influence on the subsequent behaviour of a variety. If his judgment has been at fault or hasty, a variety might be distributed which, in the course of a few generations, would show evidence of different types. The common error, particularly amongst farmers, is to regard this as "a natural law of reversion"; in effect it is nothing more nor less than the natural process of segregation; it is not a process of deterioration, but, as shown above, it merely leads eventually to the production of a population of different lines or varieties. To rectify such trouble selection is then necessary to isolate individual strains which conform to the desired type, test their comparative value, and proceed with the strain which proves most desirable.

At this stage it is expedient to refer to the practice of plant improvement by selection. First and foremost it must be emphasised that such practice is only possible when the variety from which the selections are to be made consists not of a pure-line, but of a mixture of pure-lines. The procedure is simple, for it merely involves selection of individual plants, the growth of their progeny in test rows for comparative purposes, and the subsequqent multiplication

---

*The ratios are probably more easy to follow if each plant is assumed to produce a given number of seeds, say 40. Then the F1 plant, which is of constitution *Aa*, will produce 40 plants distributed in the ratio of 1 : 2 : 1, that is, 10 plants of the constitution *AA*, 20 plants of the constitution *Aa*, 10 plants of the constitution *aa*. If each plant produces 40 seeds the following generation the 10 *AA* plants will give 400 *AA* plants, and similarly the 10 *aa* plants will give 400 *aa* plants, but the progeny of the 20 *Aa* plants will continue to segregate, and will produce 800 plants in all, 200 of which will be *AA*, 400 *Aa*, and 200 *aa*. Thus the total of *AA* and of *aa* plants for this generation will each be 600, whilst the total *Aa* plants will be 400. The progeny is, therefore, 600*AA* : 400*Aa* : 600*aa*, which is according to the ratio 2 : 3, the *Aa* plants representing 12½ per cent. The other ratios follow similarly.

of the most promising line for distribution. This conforms with the above explanation, and the object of selection is always to isolate pure-lines; having isolated them their multiplication can be proceeded with without much risk of them proving to be other than fixed for the type selected.

If, however, selections are taken from a variety which is true to type, no success can be expected. In any such variety it is well known that there exists a certain variation between individual plants. These minor variations are known as fluctuating variations. For instance, there are large ears, intermediate-sized ears, and comparatively small ears in every crop. By continuously selecting the large ears from a fixed variety from one generation to another it is not possible to obtain a variety which will yield all large ears, nor is it possible to raise the average size of the ears of a pure variety. Similarly, selecting non-infected plants from a fixed variety susceptible to a particular disease does not help in the production of a disease-resistant type, for the offspring will give the same comparative infection as the parent variety under similar conditions.

STABILITY OF THE VARIETY.

From the preceding paragraphs it is to be inferred that a state of stability exists in all fixed varieties. If it were possible to exclude agencies such as mechanical mixture and mutation, and guarantee complete self-fertilisation, then all varieties could be kept stable indefinitely, and with little trouble, for hereditary constancy could then be explicitly relied upon.

The idea that a long-established variety, which has been fixed and grown for many years, is liable to "break up" or "tend to vary" suddenly, without the intervention of external irregularities has no evidence whatever to support it; indeed, it is essentially erroneous to assume that it still possesses the inherent capacity to vary.

It is equally fallacious to regard such varieties as capable of "reversion," a term that has been used so glibly, loosely, and inaccurately that its true meaning is almost lost. A recapitulation of the foregoing would prove that fixed varieties are incapable of reverting to their original ancestors. There are no known means whereby reversion can occur except as a result of crossing or mutation, and it is a manifestation very clearly explained in the light of genetics. If, for instance, two varieties are crossed, and if their constitutions are such as to ensure a combination of factors which represent the constitution of some original type, then the resultant individual will possess the characters of the original stock, and a genuine case of reversion would be revealed. By way of example, by crossing a white sweet pea of a certain constitution with a white sweet pea of a complementary constitution, the offspring will not be white, but red. In this case factors are brought together which determine the expression of red color which was the original type. The parents, however, show no indication of this original strain, both being true for white, but their progeny proves to be reversionary. It follows that the use of the word "reversion" in connection with varieties in the field is generally erroneous. Variation within an old variety that has bred true to type cannot, therefore, pertain to its hereditary characters, but it can be more definitely ascribed to mechanical mixture or to natural crossing, or to both.

Another common belief is that a variety, especially new creations, are more vigorous when they leave the plant breeder than they are in subsequent generations. This misconception is undoubtedly based upon a vague idea of what breeders refer to as heterosis, or hybrid vigor. Heterosis is a very common thing in the early stages of cross-breds, especially in the first generation, but unfortunately, its effects are merely transitory, and it cannot be fixed. In point of fact, hybrid vigor, as its name might indicate, presupposes a heterozygous condition, so that any family of plants which is not fixed may show hybrid vigor, but when the determining factors of its constitution become homozygous, or pure, all trace of hybrid vigor is lost. In crops such as wheat, oats, and barley, which are self-fertilised, there is no known mechanism whereby use of heterosis can be made; it disappears rapidly after the first generation and is entirely lost by the time the variety is fixed. Consequently the only conclusion to arrive at is that once a self-fertilised variety is breeding true it does not possess any hybrid vigor whatever, even though it might be only one or many generations removed from the plant breeder.

The identity and purity of the already existing varieties is maintained by selection, comparative testing, multiplication, and careful handling of the lines, a duty of the plant breeders. When it leaves the stud rows and reaches the farmer certain agencies come into operation which militate against the maintenance of purity. As the stability of the variety depends upon these agencies, they are succinctly given below.

(1) External agencies leading to mechanical mixture. These are due to several influences, the chief of which arise—(*a*) during pickling or dusting, (*b*) during drilling and seeding operations generally, (*c*) at harvest time, and (*d*) when grading; or from (*e*) self-sown grains, (*f*) grains in horse-droppings, and (*g*) the use of old bags, &c.

(2) Internal or natural agencies such as (*a*) natural crossing between adjacent varieties, or between the variety and any stranger which may have intruded as a result of any of the causes of mixture. Natural crossing, however, is low, but it is feasible to suppose that considerable variation ultimately results from the process in the field. (*b*) Mutation or the spontaneous appearance of "sports," which is very rare and would only account for a very minute part of varietal mixture. (*c*) Other genetical instability which gives rise to forms such as fatuoids in oats, speltoids in wheat, &c.; this, too, is comparatively insignificant compared with other factors.

These agencies are, practically speaking, unavoidable on the average farm; time and expense are the limiting factors; even so, certain general precautions should be taken, such as care in the purchase of pure seed, the cleaning of farm machinery when dealing with grain intended for seed, and so on. It is quite a simple matter for the farmer to keep his variety reasonably pure by a system of bulk selection, that is, by selecting a large number of plants from the crop which conform to the characteristics of the variety, bulking the seed and growing it in multiplication plots. The facilities on the average farm, however, are not very adequate, and usually the process of keeping varieties pure indefinitely becomes too expensive.

SUMMARY.

(1) The cereal varietal question is often libelled through lack of fundamental knowledge with regard to the concept of a variety from the point of view of purity and stability.

(2) Once a variety is fixed for certain characters it is regarded as a pure-line as far as those characters are concerned, and whilst ever self-fertilisation remains absolute it will breed true to type; it will be neither capable of improvement nor deterioration.

(3) There is an allowable agricultural definition of the word "variety" which does not conform strictly to the theoretical constitution of a pure-line. A variety might be defined as a group of plants sufficiently homogenous to constitute a distinct unit which has inherent differences of both physiological and morphological characters that make it readily distinguishable from any other such group of plants.

(4) The purity and stability of a variety is based upon a principle governed by the laws of inheritance, which implies that where self-fertilisation is allowed to proceed without selection, the resultant plant population, after a few generations, will approach complete homozygosity. In other words, a self-fertilised population of plants eventually becomes a mixture of pure-lines.

(5) Plant breeding methods are based on this principle, but to hasten fixation, isolation and perpetuation of certain desirable types is practised from one generation to another until the process evolves a new variety.

(6) A properly fixed variety is inherently just as vigorous many generations removed from the plant breeder as it is when it first leaves his hands, evidence to the contrary is entirely lacking.

(7) When two varieties, whose constitutions are such as to bring about an association of factors which will give expression to the characters of an aboriginal stock, are crossed, true reversion to the ancestral type will occur. The use of the word "reversion" to explain certain irregularities which might exist in varieties in the field is essentially erroneous.

(8) The maintenance of purity after a variety leaves the plant breeder is militated against by both external agencies, which lead to mixture, and internal agencies such as natural crossing, mutation, &c.

(9) Selection within already established varieties does not aim at improvement but at maintaining the variety true to type, true to name, and stable in performance.

AGRICULTURAL EXPERIMENTS IN SOUTH AUSTRALIA.

[By R. C. Scott, Supervisor of Experimental Work.]

(Continued from page 1376.)

EXPERIMENTS IN THE LOWER NORTH.

Apart from miscellaneous experiments dealing with the use of sodium chlorate for the destruction of harmful weeds, the agricultural experiments in progress in this area consist of superphosphate and variety trials with wheat crops at Brownlow and manurial trials with vines in the Clare and Watervale districts.

Both these tests have been recently inaugurated, those at Brownlow being commenced in 1930 and those at Clare and Watervale in 1931. Consequently no conclusions can be drawn from the results obtained. Moreover, it should be borne in mind that the effect of manurial experiments on vines will probably be more apparent in the second year, when their influence on the production of fruit-bearing wood should be more in evidence than in the first year of application.

Typical Brownlow country before clearing.

BROWNLOW EXPERIMENTAL PLOTS.

CONDUCTED ON THE FARM OF MR. G. H. BIAR.

Brownlow is situated on the fringe of the Murray Flats, being about 12 miles south-east of Eudunda and six miles south of Sutherlands. According to the distance travelled toward the east from the range of hills extending from Truro to Eudunda, so does the average rainfall become less and less, and in round figures is reduced by about an inch per mile, reaching a minimum of between 9ins. to 10ins. per annum on the Murray Flats proper.

No official gauge is placed at Brownlow, but the amount recorded at Sutherlands will approximate very closely to that registered on the experimental plots. The soil of the district is of fertile nature, being a red loam type, and in a classification would be included amongst the red brown earth class. In its virgin state the land carried large mallee timber, together with a limited amount of bushy undergrowth. With adequate rainfall conditions this country is capable of carrying very good wheat crops, but because of the relatively heavy nature of the soil it does not respond to the light rainfall as well as land of more sandy type.

Rainfall at Sutherlands.

	1930. Ins.	1931. Ins.	Mean, 1897-1931. Ins.
January	0·00	0·37	0·35
February	0·40	0·00	0·53
March	0·04	0·37	0·66
April	0·73	2·02	0·55
May	0·41	1·64	1·20
June	0·38	1·92	1·41
July	2·05	1·17	1·02
August	2·51	0·91	1·29
September	0·72	1·59	1·23
October	2·61	0·35	1·04
November	0·48	0·52	0·79
December	0·41	0·77	0·73
Totals	10·74	11·63	10·80

Useful Rainfall.

	1930. Ins.	1931. Ins.	1897-1931. Ins.
Seeding Rains (April-May)	1·14	3·66	1·75
Winter Rains (June-July)	2·40	3·09	2·43
Spring Rains (August-September)	5·84	2·85	3·56
Early Summer (November)	0·48	0·52	0·73
Totals	9·86	10·12	8·47

The mean total rainfall calculated over a 34-year period is seen to be 10.80 inches.

In the two seasons during which the experiments have been in progress this average figure was approached in 1930 and exceeded by 83 points in 1931. However, in the matter of Useful Rainfall both years have benefited by falls amounting to considerably above the average, but each was characterised by unusual climatic conditions occurring at some period during the growth of the crop.

In 1930 the month of September proved particularly severe and the climatic conditions experienced at that time militated against maximum yields. In 1931 the rainfall for October and November was considerably below the average, but fortunately steady ripening weather obtained, and crops matured satisfactorily.

With a total rainfall of 10.80 inches and useful rainfall of 8.47 inches this district must be regarded as somewhat risky for wheat-growing operations.

Manurial Experiments at Brownlow.

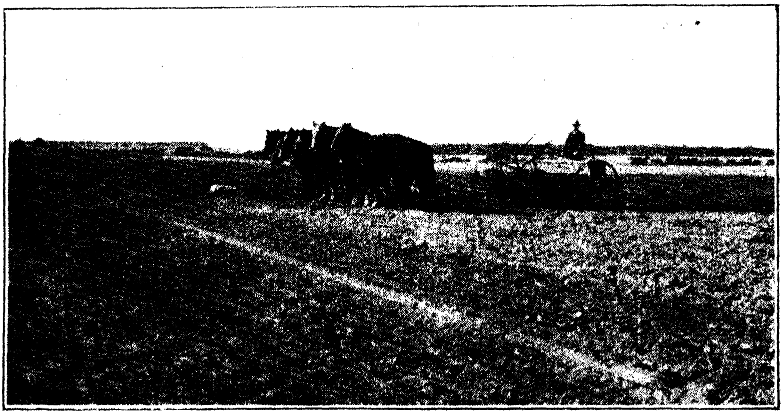
	No Manure.		½cwt. 45 Grade Super. (11½lbs. P_2O_5).		1cwt. 45 Grade Super. (23lbs. P_2O_5).		1½cwts. 45 Grade Super. (34½lbs. P_2O_5).		2cwts. 45 Grade Super. (46lbs. P_2O_5).	
	B.	L.	B.	L.	B.	L.	B.	L.	B.	L.
1930	4	28	5	19	5	29	4	52	5	27
1931	11	47	12	1	13	8	14	58	14	58
	8	7	8	40	9	18	9	55	10	12

For the two seasons in which the experiments have been in progress the average yields have increased with heavier dressings of superphosphate. However, in no case has the difference been appreciable, and at current prices would not meet the expense of the additional fertiliser utilised.

Wheat Varieties—Brownlow.

	1930.		1931.		Mean, 1930-31.	
	B.	L.	B.	L.	B.	L.
Nabawa	3	58	13	8	8	33
Begum	6	37	9	19	7	58
Canberra	3	50	10	17	7	3
Sultan	3	37	9	57	6	47
Federation	3	56	8	53	6	24
Gluyas	5	5	7	30	6	17
Sword	—		9	27	—	
Gluford	—		8	54	—	

The yields from Federation and Sultan may be regarded as the basis for comparison for wheat varieties, as with the exception of Gluyas, the remainder are comparatively new to the district. In 1930 the best yields were secured from Begum and Gluyas, whilst this year Nabawa, Canberra, Sultan, and Sword headed the list.



Seeding the Experimental Plots at Brownlow.

In the two seasons the best averages were obtained from Nabawa (8bush. 33lbs)., Begum (7bush. 58lbs.), and Canberra (7bush. 3lbs) respectively.

These are all recent introductions to the Brownlow district, and appear likely to displace the varieties previously grown.

CLARE EXPERIMENTAL PLOTS.

The experiments in the Clare district are associated with the manuring of vines and are situated at three centres, each varying in soil type and variety of vine planted.

The men conducting the work and the areas on which the plots are placed are:—*Mr. E. H. Mattner,* hilly country east of Clare; *Mr. G. Neate,* Stanley Flat; and *Mr. N. Reid,* Watervale.

The tests are therefore somewhat widely scattered, but were designed with the object of including the three main classes of soil to be found in the district.

The work was only commenced last year, and consequently the results of but a single season are available. However, in order to provide information on the experiment it was considered advisable to publish the details of the work in progress, though a discussion on the results obtained is not possible.

Rainfall at Clare.

The annual rainfall at Clare is 24.54 inches, whilst that received at Watervale is about 2½ inches more, totalling 26.91 inches per annum.

The amount recorded in 1931 was slightly below the mean, whilst the season was characterised by a severe frost which occurred in early October, followed by dry conditions extending through the remainder of the year and continuing until the middle of February of 1932.

The monthly rainfall for 1931, together with the mean fall at Clare over the past 69 years, is as follows:—

Month.	Rainfall. 1931. Ins.	Mean, 1863-1931. Ins.
January	0·68	0·85
February	0·18	0·83
March	1·46	1·01
April	2·50	1·91
May	3·16	2·95
June	4·08	3·36
July	3·59	3·10
August	3·22	3·08
September	2·80	2·84
October	0·75	2·15
November	1·15	1·30
December	0·65	1·16
Total	24·22	24·54
	1932.	
January	0·21	
February	2·02	
March	1·72	

EXERIMENTS ON THE PROPERTY OF MR. E. H. MATTNER.

Mr. Mattner's property is situated in hilly country about two miles to the east of the township. The soil is of relatively heavy nature. It is red in color and contains appreciable quantities of ironstone gravel.

The variety of vines utilised was Pedro, which were spur pruned.

The plots consisted of two rows of vines interspaced by two buffer rows, but in order that each should receive its full dressing of manure the fertiliser was distributed over three divisions in every case.

The vines made good growth during the season, and because of the locality escaped the October frost.

The plan of experiment and the results obtained at the 1932 harvest are as follows:—

Treatment and Manure per Acre.	Total Yield per Plot. Lbs.	Beaume Test.
No Manure	156	15
3cwts. Superphosphate	416	15·5
3cwts. Superphosphate 1cwt. Sulphate Ammonia	420	15·5
3cwts. Superphosphate 1cwt. Sulphate Ammonia 1cwt. Sulphate Potash	334	15·5
1 ton Gypsum	419	15
4 tons Marl (Local Deposit)	407	16
Green Manure (Pease)	356	15

The marl was secured from a local deposit adjoining Mr. Mattner's property, which when analysed by the Director of Chemistry was shown to contain 31 per cent. of lime (CaO). Ordinary agricultural lime contains 45 per cent. of CaO, and after taking the relative fineness of division into account it was considered necessary to apply a dressing of 4 tons per acre to have approximately equal effect to 1 ton of lime.

EXPERIMENTS ON THE PROPERTY OF MR. N. REID.

Mr. Reid's property is placed a little to the south-east of the Watervale township, and is typical of the limestone soils of that area. Unfortunately no results are available from this series, as the frost experienced on October 4th was particularly severe, and not a leaf was left on the vines. Consequently, whilst a light crop was eventually secured, the plots were not harvested individually.

The plan of experiment in progress consists of the following:—

Block.	Treatment and Manure per Acre.
1	No Manure.
2	3cwts. Superphosphate.
3	3cwts. Superphosphate. 1cwt. Sulphate Ammonia.
4	1cwt. Sulphate Ammonia. 3cwts. Superphosphate. ½cwt. Sulphate of Potash.
5	Green Manure (Pease).

EXPERIMENTS ON THE PROPERTY OF MR. CHAS. NEATE.

The plots are situated at Stanley Flat, about 2½ miles north of Clare. The soil is a deep, chocolate-colored loam. The vineyard was planted with Zante Currants in 1910 and the trellises are 11ft. apart, with the vines spaced at 11ft. intervals in the rows. Manure has been applied in previous seasons, 187lbs. of Superphosphate being added in each of the last three years. whilst in addition 1cwt. of Sulphate of Ammonia was utilised in 1930. Frosts have been particularly severe on this area, practically destroying the crop in 1930-31, and rendering difficult the selection of suitable canes when pruning in the following year. Again last season (the first year of the test) a frost occurring on October 4th cut the young shoots and hardly a green leaf was left on the vines. However, as the season advanced they made a splendid recovery and a fair average crop was harvested.

The marl used in these tests was secured from an adjoining deposit and showed an analysis of 24.6 per cent. lime (CaO). Consequently an application of 5 tons per acre was considered necessary.

The superphosphate was drilled into the soil prior to ploughing, whilst the gypsum and lime were spread over the land after ploughing and harrowed in.

The results obtained were as follows:—

Treatment and Manure per Acre.	Total Yield per Plot. Fresh Fruit. Lbs.	Dry Fruit. Lbs.	Weight of Cuttings. 1931. Lbs.	1932. Lbs.
No Manure	4,032	1,180	133	129
3cwts. Superphosphate	5,346	1,568	152	152
1 ton Gypsum	4,180	1,170	168	168
5 tons Marl	5,742	1,675	171	173
Green Manure	3,938	1,148	158	172

Each plot consists of 120 vines, planted 11ft. apart in each direction, and therefore the area covered in every case is one-third of an acre.

AGRICULTURAL EXPERIMENTS ON YORKE PENINSULA.

Several series of Agricultural experiments are in progress on Yorke Peninsula. Those connected with the Manganese Deficiency of Soils have already been reported on, and the results were published in a previous issue of the *Journal of Agriculture* (Volume XXXV., No. 7).

The remaining tests deal with manurial and variety trials with wheat and malting barley, and are situated at Urania, South Kilkerran, and Brentwood. The experiments at Urania have been in operation for the longest period, and were commenced in 1927, whilst those at South Kilkerran and Brentwood have only been in progress for two and one year respectively.

The three first-named districts adjoin each other, lying from 7 to 10 miles south to south-east of Maitland. The most central official rainfall recording station is at Port Victoria, which lies about 7 miles to the eastward of these areas. However, the rainfall received on the experimental plots would approximate very closely to that recorded at Port Victoria, and therefore it has been decided to publish the records of that station as indicating the rainfall conditions under which these tests are being conducted:—

Rainfall at Port Victoria.

Totals	9·56	9·84	11·23	11·82	14·06	11·31	13·08

The above tables indicate the total and useful rainfall recorded during the past five years comparatively with the means for 1927-31 and 1879-31. It will be noted that for the five seasons during which the Urania plots have been in existence the total rainfall has been 1.34 inches below the mean for the district. In 1929 the amount recorded exceeded the average, largely because of exceptionally heavy rains occurring in the month of December. The 1931 fall was practically equal to the mean, but that for each of the remaining three years was considerably lower. The Useful Rainfall table shows that last season was very satisfactory in this respect, as the amount recorded was practically an inch above the normal precipitation. However, the other years have been relatively poor, and vary from 3¼ to 1¼ inches below the average.

The respective seasons have each been characterised by special features, which may be summarised as follows:—

1927.—Relatively poor seeding conditions, followed by a dry September and October, which reduced crop yields.

1928.—Throughout the year the rainfall was below average, but crops made fair headway until a dry August checked development.

1929.—In this season exceptionally poor rains during the month of October, accompanied by warm weather, hastened maturity and depreciated crop returns.

1930.—Satisfactory opening rains were not received until early in July. Warm summer conditions were experienced in November, and therefore the crops were permitted only a short growing period.

1931.—Favorable conditions prevailed throughout the year until the month of October. Fortunately the weather remained cool and crops matured well.

EXPERIMENTS ON THE PROPERTY OF MR. A. W. KELLY, URANIA.

Mr. Kelly's farm is situated immediately to the south-west of the Urania township, and is placed in country typical of much of the better-class land on Yorke Peninsula.

Before clearing it carried medium sized mallee timber with abundance of bushy undergrowth.

The soil itself is of limestone nature overlying loose limestone rock, which in many fields accumulates on the surface and necessitates removal. It is fertile in nature and capable of producing high yields of good quality grain.

The experimental plots comprise tests with manures and wheat varieties, and have promoted considerable interest amongst farmers of the district.

Manurial Experiments, Urania.

Year.	No Manure.		½cwt. 45 Grade Super. (11½lbs. P_2O_5).		1cwt. 45 Grade Super. (23lbs. P_2O_5).		2cwts. 45 Grade Super. (46lbs. P_2O_5).		3cwts. 45 Grade Super. (69 lbs. P_2O_5).	
	B.	L.	B.	L.	B.	L.	B.	L.	B.	L.
1927	7	56	10	15	10	34	12	20	13	16
1928	4	33	6	29	8	38	9	45	10	45
1929	8	49	11	5	18	50	19	54	22	5
1930	10	19	13	35	15	3	16	18	16	32
1931	25	55	33	25	31	55	35	55	36	2
Means, 1927-1931	11	30	14	58	17	0	18	50	19	44
	£ *s.* *d.*		£ *s.* *d.*		£ *s.* *d.*		£ *s.* *d.*		£ *s.* *d.*	
Value at 3s. 4d. per bush.	1 18 4		2 9 11		2 16 8		3 2 9		3 5 9	
Net Value with Super. at 5s. per cwt.	1 18 4		2 7 5		2 11 8		2 12 9		2 10 9	

The yields obtained from the different plots have been very regular so far as their respective positions are concerned, as with the exception of 1931 they have gradually increased according to the additional quantity of Superphosphate applied. The highest return has been secured from the 3cwt. dressing, namely, 19bush. 44lbs. per acre, with 18bush. 50lbs., 17bush., 14bush. 58lbs., and 11bush. 30lbs. for the 2cwt., 1cwt., ½cwt., superphosphate and No Manure plots respectively.

When these yields are converted to a cash value by allowing 3s. 4d. per bushel for the grain and 5s. per cwt. for the superphosphate, the maximum profit follows the 2cwt. manuring. This plot has returned 1s. 1d. per acre more than the 1cwt. and 2s. per acre more than the 3cwt. dressing.

On the above basis, therefore, it would appear that the limit for profitable Superphosphate manuring lies within the vicinity of 2cwts. per acre.

In addition to the Superphosphate experiments, a plot receiving phosphoric acid equivalent to the 2cwt. dressing, but also obtaining 5½lbs. of Nitrogen and 5lbs. of Potash per acre was included.

The object was to ascertain whether wheat would respond to dressings of a complete fertiliser, but in the two seasons in which the test has been conducted the yields have been 16bush. 21lbs. and 35bush. 5lbs., comparatively with 16bush. 18lbs. and 35bush. 55lbs. per acre from 2cwt. superphosphate dressing only. There is, therefore, very little difference in the respective returns, and apparently the addition of either Nitrogen or Potash is of little value to wheat crops in this district.

WHEAT VARIETY EXPERIMENTS.

Mr. Kelly is particularly interested in the variety experiments, and from time to time has included additional varieties for seeding in this test. Consequently it is not possible to calculate the averages for all wheats over the five-year period, and therefore two sets of means are shown in the following table.

Wheat Varieties, Urania.

Variety.	1927.		1928.		1929.		1930.		1931.		Means., 1927-31.		Means., 1929-31.	
	B.	L.	B.	L.	B.	L.	B.	L.	B.	L.	B.	L.	B.	L.
Nabawa	18	45	11	17	20	6	19	32	34	47	20	53	24	48
Caliph	18	51	9	45	19	54	16	18	35	55	20	9	24	2
Sultan	16	59	8	36	21	29	17	30	32	43	19	27	23	54
Gluford	17	20	11	21	15	56	17	46	32	42	19	1	22	8
Waratah	16	23	10	42	18	31	17	26	31	18	18	52	22	25
Dan	16	11	11	24	17	59	17	1	30	56	18	42	21	59
Daphne	14	52	10	21	19	57	16	32	30	56	18	32	22	28
Nawab	—		—		20	43	17	54	37	2	—		25	13
Sword	—		—		22	52	18	30	33	11	—		24	51
Begum	—		—		21	31	14	52	33	8	—		23	10
Ford	—		—		18	33	17	21	33	20	—		23	5
S.H.J.	—		—		—		17	47	30	18	—		—	
Jones Wonder	—		—		—		—		34	33	—		—	

Examination of the yields over the five-year period shows that Nabawa is at the head of the list with 20bush. 53lbs., followed by Caliph 20bush. 9lbs. and Sultan 19bush. 27lbs.

Comparing the varieties included in this mean, it would appear that the three mentioned are the most valuable for the district and are to be preferred to either Gluford, Waratah, Dan, or Daphne.

Caliph has given the highest return in two out of the five seasons under review, whilst Nabawa and Sultan have each headed the averages on one occasion. They are all well-known varieties, and their ability to thrive in limestone soils and ripen their grain under adverse seasonal conditions is generally recognised. However, when the means for the three years, 1929, 1930, and 1931, which includes new varieties, are considered, it will be seen that they have been displaced by both Nawab and Sword. The latter is only a few pounds ahead of Nabawa, but Nawab has exceeded the average for this wheat by the appreciable amount of almost half a bushel per acre. Both were bred at Roseworthy Agricultural College, where they exhibited considerable promise in the seed plots. Nawab was produced by crossing Anvil (King's White x Jonathan) with Sultan, whilst Sword is the result of mating Sultan (King's White x Caliph) with Ford. The results obtained with these two varieties both at Urania and in other parts of the State are most satisfactory, and lead one to think that they will eventually prove very valuable wheats for the limestone soils of South Australia.

EXPERIMENTS ON THE PROPERTY OF MR. W. A. HEINRICH, SOUTH KILKERRAN.

The work being conducted by Mr. Heinrich consists of a series of tests laid down with the object of determining the influence of various manurial dressings on the yield and malting quality of Prior barley.

Work was commenced in 1930, and therefore we have the results from two seasons to tabulate, but the period is too short to allow comment on the yields obtained.

The climatic and soil conditions under which these experiments are placed are very similar to those at Urania.

Manurial Experiments with Pryor Barley.

Manure per Acre.	1930.		1931.		Means. 1930-31.	
	B.	L.	B.	L.	B.	L.
No Manure	22	25	24	9	23	17
½cwt. 45 per cent. Super. (11½lbs. P_2O_5)	24	11	27	4	25	33
1cwt. 45 per cent. Super. (23lbs. P_2O_5)	25	3	25	25	25	14
1½cwts. 45 per cent. Super. (34½lbs. P_2O_5)	26	34	29	6	27	45
2cwts. 45 per cent. Super. (46lbs. P_2O_5)	26	29	29	34	28	7
2cwts. Complete Orchard Manure (29lbs. P_2O_5, 11lbs. N., 10lbs. K.)	26	2	30	16	28	9
1cwt. 45 per cent. Super. (23lbs. P_2O_5) 56lbs. Sulphate Ammonia (11lbs. N.)	25	11	29	49	27	30
1cwt. 45 per cent. Super. (23lbs. P_2O_5) 45lbs. Chloride Ammonia (11lbs. N.)	—		29	49	—	

In both seasons the barley has been seeded on wheat stubble land

There is no appreciable difference in the yields from the various plots which have received the fertilisers, although that secured from the 1cwt. of Superphosphate plot in the 1931 harvest appears to have been depressed by some unexplained factor.

Each season Mr. A. G. Barrett, of Messrs. Barrett Bros., maltsters, of Adelaide, has kindly examined the grain harvested and expressed an opinion as to the malting quality of the various samples. The substance of his remarks is as follows—

1930.—"These are all good samples and do not exhibit great variation. So far as the best malting grain is concerned, two samples may be bracketed together, namely, that from the plot receiving 1cwt. of Superphosphate plus ½cwt. of Sulphate of Ammonia and that from the 1½cwts. of Superphosphate dressing only. However, the barley from the Ammonia plot is slightly fuller. Applications of 1cwt. of superphosphate, ½cwt. superphosphate, and 2cwts. of Complete Orchard Manure have produced grain of similar quality, and these samples may be grouped together. The poorest barley is that harvested from the 2cwts. of superphosphate and No Manure plots, but the differences between any of the samples are not great."

1931.—"The order of quality appears to be 1cwt. Superphosphate, plus 45lbs. Chloride of Ammonia; 2cwts. Complete Orchard Manure; 1cwt. Superphosphate plus 56lbs. Sulphate of Ammonia; ½cwt. Superphosphate; 1½cwts. Superphosphate; No Manure; 2cwts. Superphosphate; 1cwt. Superphosphate.

The Complete Orchard Manure, Chloride of Ammonia, and Sulphate of Ammonia dressings have all led to improvement over the superphosphate only plots, particularly regarding the regularity and plumpness of the grain. There is little difference between the barley from these three manurings, but probably that from the Complete Manure was the best and that from the Chloride of Ammonia slightly better than that from the Sulphate of Ammonia plot.

The grain from the 1cwt. of Superphosphate plot varies from the remainder and appears to be affected by some factor other than the quantity of manure used."

EXPERIMENTS ON THE PROPERTY OF MR. O. H. HEINRICH, SOUTH KILKERRAN.

The object of the experiments in progress on the property of Mr. O. H. Heinrich is to ascertain whether it is possible to secure malting barley varieties which would be an improvement on the type now being grown on Yorke Peninsula, namely, Prior.

In this connection small quantities of seed of nine varieties were imported into South Australia, five being secured from the Department of Agriculture in New Zealand as representing the best barleys in that country, and four from Mr. H. Pye, Cerealist at Dookie Agricultural College, Victoria.

These were seeded comparatively with Pryor and the results secured over the last two seasons are shown in the following table:—

Malting Barley Variety Experiments.

Variety.	1930.		1931.		Means, 1930-31.	
	B.	L.	B.	L.	B.	L.
Early Challenger	17	14	32	44	25	4
Prior	16	46	28	0	22	23
Bevan Special	13	16	24	46	19	6
Kinver Chevalier	14	5	22	16	18	11
Plumage	14	2	21	37	17	45
Plumage Archer	12	16	22	2	17	9
Goldthorpe Spratt	11	11	20	26	15	44
Archer Spratt	14	6	—		—	
Spratt's Archer	12	4	—		—	
Danish Archer	8	23	—		—	

In both years the highest return has been harvested from Early Challenger, a variety obtained from Victoria, and on the averages this barley has exceeded the yield from Prior by 2bush. 32lbs. per acre.

THE most carefully prepared dishes may be spoilt if the kerosene in your Perfection stove is inferior.

Laurel Kerosene climbs the wick readily and leaps into a blue gas-like flame, giving abundance of clean, live, economical heat.

No wonder 50,000 housewives in Australia and New Zealand who use Laurel in their stoves acclaim its dependability, cleanliness and uniformity.

When ordering kerosene ask definitely for *Laurel.*

LAUREL

Kerosene

Ideal for Lighting, Heating and Cooking.

THE VACUUM OIL COMPANY PTY. LTD.

The remaining types are much later in maturing than either Early Challenger or Prior, and therefore in each year they have encountered relatively unfavorable conditions for developing their grain.

The samples obtained from the different varieties were submitted to Mr. Barrett, who expressed the following opinion:—

1930.—"Goldthorpe Spratt is a very even and attractive grain, and if a little better filled would be a first-class barley. Plumage Archer is but slightly inferior to Goldthorpe Spratt. Early Challenger, Plumage, Kinver Chevalier, and Bevan Special are all good barleys and very difficult to separate. Early Challenger has yielded grain very similar to Prior in characteristics. I would place these four varieties in on a lower grade than either Plumage Archer or Goldthorpe Spratt.

The remaining samples are not equal to those mentioned above, and judged on the merits of the grain submitted do not appear worth continuing with."

1931.—"Provided that well developed grain can be regularly produced under our soil and climatic conditions, the following varieties are of good malting type:—

Plumage.
Plumage Archer.
Scotch Plumage.
Bevan Special.
Goldthorpe Spratt.
Early Challenger.

The latter is very similar to Prior except that the basal bristle is slightly less hairy."

In both years Mr. Barrett has pointed out the similarity of the grain from Prior and Early Challenger varieties, and examination in the field has led us to the conclusion that the latter is a selected strain of Prior barley.

It is therefore of the type familiar to maltsters, and as it has the highest average yield appears to be the most valuable of the barleys included in the experiments. Prior has now been grown for a number of years and is the leading malting barley in South Australia, but largely because there is no cereal breeding station established in a malting barley district very little work has been done in the isolation and building up of superior strains.

Probably work of this nature would be more important than attempting to introduce new varieties, as even if these were successful, so far as yield is concerned, they may be difficult to establish if they should necessitate any alteration to the plant of the malthouse. The selection of Prior barley has now been taken in hand at Roseworthy Agricultural College. Several strains are being built up, and when sufficient grain is available arrangements will be made for testing them on Yorke Peninsula.

EXPERIMENTS ON THE PROPERTY OF MR. J. H. BOUNDY, BRENTWOOD.

Another series of variety tests were established last year on the property of Mr. J. H. Boundy, which is situated about seven miles to the south-west of Minlaton and almost on the instep of the Peninsula.

Malting Barley Variety Experiments, 1931.

Variety.	Yield per Acre.	
	B.	L.
Early Challenger	35	26
Prior	32	33
Plumage	24	17
Kinver Chevalier	23	33
Scotch Plumage	21	31
Plumage Archer	20	13
Scotch Maltster	20	2

Here again Early Challenger has given the highest yield, although it obtained some advantage from the fact that weather delayed seeding for some days after this variety was drilled in.

Included in this test were two varieties imported from England, namely, Scotch Plumage and Scotch Maltster. The yields were not very satisfactory, but they may improve as they become more acclimatised.

DESTRUCTION OF TREES AND THE EFFECT ON RAINFALL.

[By E. BROMLEY, Divisional Meteorologist.]

The effect of the destruction of trees on rainfall (and climate generally) should be examined from two aspects—

1. The effect on the country *surrounding* the area on which the trees were located, *i.e.*, adjacent effect.

2. The effect on the country over which the trees were located, *i.e.*, local effect.

The necessity for a distinction follows from the obvious deduction that if a forest were not destroyed the country would be of very little economical value for anything other than a forest.

In regard to (1) statistical evidence is not satisfactory, but what is available supports the view that rainfall over open country is *not affected* by the destruction of a neighboring forest.

In regard to (2) statistical evidence suggests that the existence of a forest *increases* the rainfall by a very small amount—*about 2 per cent.*—over the country on which it is located.

The theoretical considerations in this aspect are as follows:—

(*a*) A compact mass of trees, say 30ft. high, increases the effective height of the country by that amount, and would consequently increase the tendency for orographical rain. This is perhaps the most important point, and is responsible for the greater portion of the effect.

(*b*) The greater friction of the wind with the tree surface compared to open ground may lead to a very slight increase in rainfall.

(*c*) In favorable mountain situations a slight increased supply of water may be collected mechanically from the clouds which envelop the forest.

(*d*) Under favorable conditions a slight increase in prevailing humidity may increase the rainfall slightly. This would probably occur only in an already wet climate.

The most satisfactory evidence in regard to aspect (2) is derived from an experiment at Waggon Wheel Gap, Colorado, U.S.A.

Two similar watersheds of about 200 acres extent, equally covered with forests, were selected and observations carried out for seven years. One area was then deforested and observations continued for another seven years.

The result of the investigations showed a net *decrease* of 40 points in an annual average rainfall of 21in., or about 2 *per cent.* over the deforested area.

Some results from an investigation in Sweden also suggest an increase of about 1 per cent. due to the presence of a forest, and in Germany some results indicated a probable increase of 1 to 2 per cent. in the rainfall.

It is interesting to note that theory suggests that the replacement of forests by field crops or grass lands will increase the rainfall slightly, *i.e.*, field crops or grass covered grounds are more effective than forests in increasing transpiration of water into the air.

In support of this, an investigation by E. T. Quayle suggested an increase of three per cent. in the spring rainfall of north-west Victoria as a result of the replacement of Xerophilous forest and scrub by growing crops.

On the other hand, an examination of rainfall in two consecutive 25-year periods over the Great Plains States, U.S.A., showed the following facts:—Average rainfall for first 25 years was 19.3in.; and for the second 25 years it was 18.6in., or a *decrease* of about 3 per cent.; yet the area under crop was *increased* from 18 million acres at the end of the first 25 years to 54 million acres at the end of the second period. No data were given in respect to what forest cover, if any, existed prior to or during settlement.

Returning to Aspect (1) and the Waggon Wheel Gap experiment, the variations in the various elements between the two periods on the undenuded area were either completely negligible or of such a small order as might be expected in any two seven-year periods, *e.g.*, the rainfall increased by 13 points, or about a ½ per cent.

The destruction of the forest on the neighboring area, therefore, apparently had no effect on the adjacent country. (In fact, the wind velocity *decreased* by a very small amount; it might have been expected to *increase*).

In admitting the possibility of some slight increase over the local country, it appears obvious that the greater the area, thickness, and height of the forest, the greater will be the effect, and it seems equally obvious *that the destruction of isolated clumps of trees will pass practically unnoticed in any effect on rainfall.*

It seems an obvious deduction also that the drier the climate generally, the less likely will there be any effect, *e.g.*, a forest of, say, 1,000 acres in the Lower South-East of South Australia may produce a slight increase in rainfall in its own area; but a 1,000 acre forest in the Lake Eyre region would be quite ineffective. It should be remembered that it is the rainfall which enables a forest to grow in the first place (except that irrigation might be employed in small areas.)

It is nevertheless generally conceded that the growing of a belt of trees as a wind break is effective for some distance beyond the trees, while regulation of stream flow and reduction of erosion follow from the planting of trees, although field crops and grass lands are considered to be quite as effective as trees in the control of drainage.

It might be interesting to give the comparative figures for elements besides rainfall, from the Waggon Wheel Gap experiment, showing the effect of deforestation on the country itself, *i.e.*, Aspect (2). In addition to the 40 points decrease in rainfall, the removal of the forest cover resulted in a nett increase of about two degrees in the mean maximum temperature, an increase of about one degree in the mean minimum; an increase of 2½ miles per hour in mean wind velocity. The average date of snow melting was four days earlier, underground temperatures were from two to three degrees warmer, and there was a reduction of 5 per cent. in the relative humidity. The total run-off (stream-flow) over an extended period increased by 15 per cent., or the percentage of precipitation appearing as run-off increased from 29 to 35 per cent., while in short periods, following heavy rains, the run-off increased by 40 per cent.

Erosion was increased seven-fold, but even this may be a low figure, as such depends greatly on the nature of the soil.

SORE SHOULDERS.

The following remedy for sore shoulders, which Mr. W. J. Spafford (Deputy Director of Agriculture) said had cleared up a very serious outbreak amongst the horses at Roseworthy Agricultural College, was recommended to farmers at the Murray Lands Conference at Karoonda on August 2nd by Mr. W. G. Bennett, B.V.Sc. (Veterinary Lecturer Roseworthy Agricultural College):—Paint the shoulders with a mixture of neatsfoot oil and either white lead or zinc white, of a consistency of separated cream, to which can be added 1 tablespoonful of boracic to the pint. This should be done *every* morning before the horse goes out. Every night when the horse comes in the shoulders should be washed down thoroughly with a strong solution of salt (or wattle bark) and the collars thoroughly cleaned.

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR AUGUST.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

The work of pruning will have now been completed. All big cuts should have a coat of paint. Thoroughly clean pruning implements before putting away.

Winter treatment of trees which have been subject to fungous diseases should be completed. Use winter strength Bordeaux. Curl leaf, shot hole, and scab can be materially lessened by this treatment.

Keep watch for aphis on peach, plum, and citrus trees, and on beans. Use black leaf 40 or nico dust; early treatment saves a lot of trouble and damage.

Anthracnose on vines must be dealt with at once if any good is to result. A pamphlet may be had on application describing the method. Enclose stamp for reply.

Take off all citrus fruits showing signs of brown rot, and pick up all windfalls and destroy them.

Where it is intended to apply sulphate of ammonia or other manures, work well into the soil this month.

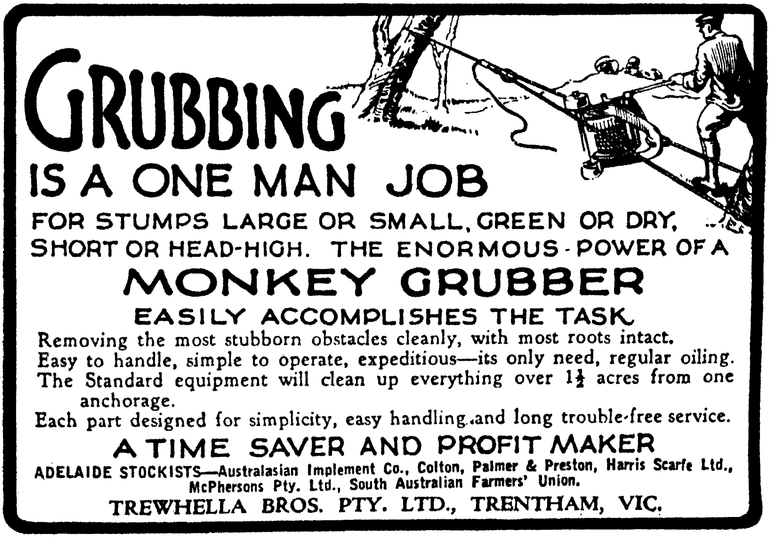
It is most important that the soil be got into good tilth as early as possible, especially about the trees and vines. We have had bountiful rains and we should do our best to make good use of them.

Keep beds of strawberries well worked.

Take out and destroy all sickly plants in the tomato-houses; keep soil loose and free from weeds, and remove all weeds from about the houses. Watch for cut-worm, and use arsenate of lead if noticed. Use nico dust for white fly.

There is no cure for Irish blight of potatoes, but it can be prevented by the use of Bordeaux mixture. The time to apply is when the plants are a few inches high; and again in a few weeks if required. The under side of the leaves must be coated with the mixture as well as the tops; it may be used wet or dry. Destroy all sickly plants.

Have spraying outfit in good order and ready for use.



GRUBBING
IS A ONE MAN JOB
FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A
MONKEY GRUBBER
EASILY ACCOMPLISHES THE TASK
Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.
Each part designed for simplicity, easy handling and long trouble-free service.
A TIME SAVER AND PROFIT MAKER
ADELAIDE STOCKISTS—Australasian Implement Co., Colton, Palmer & Preston, Harris Scarfe Ltd., McPhersons Pty. Ltd., South Australian Farmers' Union.
TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

WARTS ON UDDERS OF COWS.

Replying to the Secretary, Agricultural Bureau, Wepowie, who asked: ''What is the cause of and a cure for warts on a milch cow's udder?'' Mr. C. McKenna, B.V.Sc. (Government Veterinary Officer) says warts in cattle have been shown to be infectious. The cause is a germ. Rubbing is supposed to be the common method of spread. Warts may occasionally disappear without treatment of any kind. Most cases require treatment as follows:—(1) Warts which are small at base may be clipped off and resultant wound dressed with tr. iodine, or else they may be removed by tying a thread around them (recommended for large size warts with small base). (2) Painting daily with tr. iodine or glacial acetic acid. (Before applying latter, apply vaseline to surrounding healthy skin.) (3) Small warts as on udders of cows can be dressed daily with warm castor oil. (4) Further, in young stock (6-12 months old) give one tablespoonful of Fowler's solution of arsenic night and morning in a small damped feed. Note.—Do not give arsenic solution to milking cows, as the arsenic may pass into the milk.

DORSET HORN RAM AS A SIRE FOR LAMBS.

Reporting that a fairly high percentage of Merino ewes mated with the Dorset Horn ram had considerable difficulty in lambing, the Secretary of the Yadnarie Branch of the Agricultural Bureau asks if ewes crossed with the Border Leicester ram would have the same trouble. The Supervisor of Experimental Work (Mr. R. C. Scott) says that lambs by Dorset Horn rams are frequently particularly broad and deep in the chest, and if the ewes are young or small framed, lambing difficulties are increased. There is always a certain amount of trouble when Merino ewes are mated with Dorset Horn rams, but the larger the frame of the mother, the smaller the percentage of ewes which have to be assisted at lambing time.

The Border Leicester is somewhat differently shaped, and with his pointed face provides for a wedge-shaped presentation and, therefore, easier birth. The Southdown ram is smaller framed and, except in the case of accident, his progeny are born freely. This sire would give lambs of the best export type and less lambing difficulties would be anticipated. If either this breed or the Border Leicester were mated with Merino ewes.

PRUNING COMPETITIONS.

LOWER NORTH.

CHAMPIONSHIP COMPETITIONS.

The Championship events of the 1932 series of Pruning Competitions for the Lower North were held at Light's Pass on July 13, when there were 18 competitors in the Fruit Tree section and 25 in the Vine section. The sites chosen were Messrs. F. W. Boehm's and Bert Boehm's orchards for Fruit Trees and Mr. A. Moder's vineyard for the Vines. The Branches represented by the competitors were Angaston, Koonunga, Light's Pass, Lone Pine, Lyndoch, Penwortham, Watervale, and Williamstown. Among the competitors was Mr. Fred Boehm, the 14-year-old son of Mr. F. W. Boehm. This young man received the congratulations of competitors and visitors on his success in gaining a place in the Light's Pass local competitions, which entitled him to compete in the championship. Dr. J. Davidson and Mr. J. W. Evans, of the Waite Agricultural Research Institute, were present, and Messrs. Geo. Quinn (Chief Horticultural Instructor), H. C. Pritchard (General Secretary of the Agricultural Bureau), J. B. Harris (District Horticultural Instructor), and J. L. Williams (Viticultural Instructor, Roseworthy College) represented the Department of Agriculture.

The Lower North district covers a large area, and the Competitions entail a lot of detail work in their administration. The efforts of Branch Secretaries and Committees are therefore appreciated by those who are in any way associated with these Competitions. The competent and energetic work of the Competition Secretary (Mr. J. S. Hammat) brought the championship events to a successful termination, and he was ably assisted by Mr. L. A. Koop, of Light's Pass.

During the luncheon adjournment Dr. Davidson gave an interesting discourse on "Thrips."

TROPHIES.

At a meeting at Nuriootpa on July 29th, at which the Chairman of the Light's Pass Branch (Mr. A. Milway) presided over a large attendance, Dr. A. R. Callaghan (Principal of the Roseworthy Agricultural College) presented the trophies donated by the Royal Agricultural and Horticultural Society to the winners (Messrs. F. W. Boehm and H. Hammerling) in the Fruit Tree and Vine sections respectively. Mr. W. Langdon Parsons exhibited a cup for competition over a period of three years ending in 1933, and he also intimated that a similar trophy would be available for another three-year period commencing with the 1934 Competitions.

ROSEWORTHY AGRICULTURAL COLLEGE.

LIVESTOCK FOR SALE.

During the next few weeks the College can offer for sale the following animals from their well-known flocks:—

Berkshire Boars, from 8 weeks to 8 months old.
Berkshire Sows, from 8 weeks to 16 weeks old.
Berkshire-Tamworth Crossbred Sows.
Jersey Bulls and Bull-calves, from Tested Herd-book Cows.
Southdown Rams—Hoggets to 6-tooth.
White Indian Runner Drakes and Ducks.
White Leghorn Roosters.
Black Orpington Roosters.

— FULL PARTICULARS FROM THE PRINCIPAL. —

McLAREN FLAT.

The Annual Pruning Competitions, conducted under the auspices of the McLaren Flat Branch of the Agricultural Bureau, were held in the vineyard of Mr. J. Ingoldby on July 16th. The judges were Messrs J. B. Harris (District Horticultural Instructor) and J. L. Williams, rod section, and Messrs. G. Cox and E. Leishman (District Horticultural Instructor, spur section. Mr. H. C. Pritchard (General Secretary Agricultural Bureau) attended on behalf of the Advisory Board of Agriculture. Secretarial duties were in the capable hands of Mr. P. T. Wait, who is to be congratulated on the excellent manner in which the competitions were organised.

TWIN LAMB DISEASE.

REPORT OF EXPERIMENTAL WORK AT AGRICULTURAL COLLEGE, ROSEWORTHY.

[By A. R. Hickinbotham, B.Sc., Dip.Ed., Chemist, and W. G. Bennett, B.V.Sc., Veterinarian.]

Introductory.

In a previous paper (*Journal* of the Department of Agriculture, South Australia, July, 1931) an account was given of experimental work conducted at the College in connection with soursob poisoning. Attention was directed to similarities in symptoms of soursob poisoning and twin lamb (or twin pregnancy) disease, and the hypothesis was put forward that twin lamb disease was also associated with a lowering of the calcium content of the blood.

This, in turn, suggested the possibility of treating twin lamb disease with calcium. Certain experiments were carried out, as reported, with encouraging results.

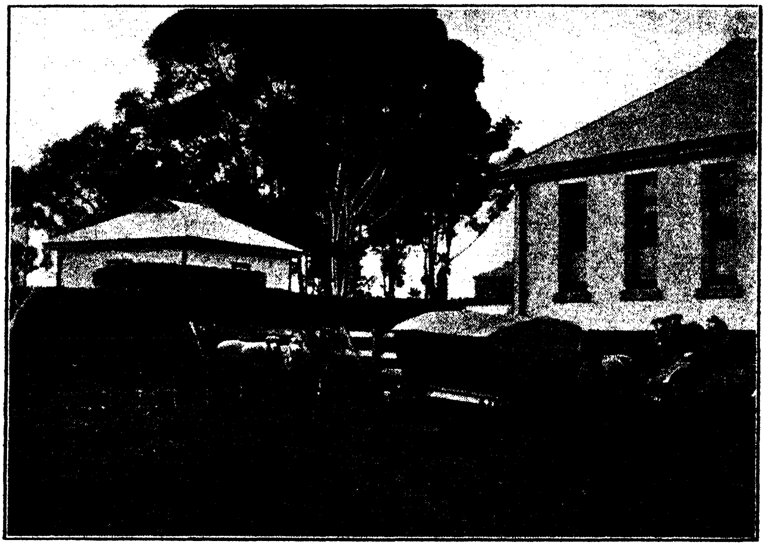

Fig. 1.—The experimental yards showing limited space and method of feeding.

Experiment, 1932.

Another experiment to test this hypothesis was planned this year, but owing to circumstances beyond control the start was made too late in the season for any measure of finality to be reached. Further, the season has been so favorable that no normal twin lamb disease cases have been reported here. At the same time, certain data obtained from the experiment may be of interest.

Forty flock ewes—all Border Leicester-Merino crossbreds excepting two Merinos—were placed in special yards and 30 were fed dry feed and exercise was limited, with the object of producing twin lamb disease, the experimental ration being, at first, cocky chaff; later, mixed straw chaff. The remaining 10 were on green feed as a control.

The only ewes available were, unfortunately, in excellent condition and close to lambing. All were subjected to a preliminary period of 14 days on dry feed, and during this period 19 lambed. They were then divided for separate treatment, but further lambing reduced the numbers rapidly.

RESULTS.

Only one death occurred, the ewe dying overnight. It was apparently normal late in the afternoon; late in the evening it was observed to be showing symptoms similar to those of twin lamb disease. Early next morning it was dead, and showed *post-mortem* changes consistent with this disease. No treatment was given in this case, which occurred in the third week.

After four weeks, calcium determinations were made on the blood of a ewe of each group, and these showed 9.2 mgms. per 100 ccs. for dry feed only, and 10.2 mgms. for dry feed with supplements (bone meal and vitamins).

After six weeks on dry feed another ewe showed symptoms which appeared to indicate the onset of twin lamb disease, but within 12 hours it had lambed. A blood sample taken gave 8.6 mgms, of calcium.

Only three ewes, which proved to be empty, now remained—two Merinos and a crossbred. These were carried on for a total period of 2½ months in an effort to show the effect, if any, of these conditions (dry feed and lack of exercise) on the calcium content of the blood. At the end of the test the Merinos gave 10.1 and 9.3 mgms., but the crossbred gave only 7.95 mgms., and its general condition was very low (Fig. 2).

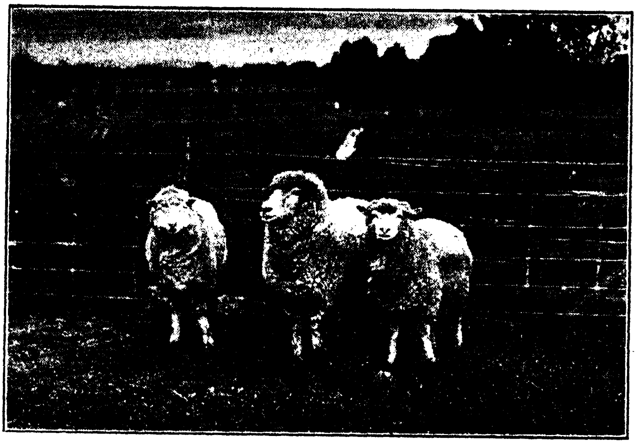

Fig. 2.—**Showing the effect on the last two crossbred ewes of 2 months on dry feed and confined space, compared with a ewe (centre) from the same flock on natural pasture continuously.**

The crossbred was turned out on to natural pasture, and three weeks later its blood calcium had risen to 9.75 mgms. Two similar crossbred ewes that had been on natural pasture continuously were tested at the same time and gave 10.8 and 11.3 mgms.

CONCLUSIONS.

While, owing to the limited number of cases examined, these results scarcely prove anything, they are, at least, not contrary to the hypothesis, and are sufficient to justify further experimental work next year.

The results suggest that prolonged dry feeding of this type and lack of exercise tend to lower the calcium content of the blood, even in empty ewes which do not have to meet the calcium requirements of a foetus. The same conditions are known to favor the occurrence of twin lamb disease.

It will be noticed that the two Merinos stood up to the conditions better than the one remaining crossbred.

ACKNOWLEDGMENTS.

We are indebted to Messrs. W. J. Spafford, Acting Principal, for interest and assistance; S. E. Whicker for general care of the sheep; and J. P. Egan.

STATE OF SOUTH AUSTRALIA.

SUMMARY OF LIVESTOCK STATISTICS, YEAR 1931.

[By W. L. Johnston, Government Statist.]

I. Sheep and Wool.

1. *Number of Sheep.*—The sheep flocks on December 31st, 1931, numbered 6,608,981 (5,980,959), increase 628,022. These were classified as follows:—Ewes, 3,287,194 (3,058,544); wethers, 1,513,377 (1,625,405); rams, 86,061 (86,122). Under one year old, 1,722,349 (1,210,888).

2. *Breeds of Sheep.*—86.4 (86.3) per cent. of the flocks were returned as pure-bred Merino and 6.3 (7.1) per cent. Merino Comebacks, 1.0 (0.9) per cent. other pure breeds (Corriedale, Shropshire, Dorset Horn, Lincoln, Romney Mash, Southdown, Suffolk, etc.), and 6.3 (5.7) per cent. Crossbreds.

3. *Lambing,* 1931.—During the year 1931 2,717,101 (2,515,293) ewes were mated and 1,983,667 (1,427,003) lambs marked, exceeding the previous record of 1,740,620 in 1925. The percentage of 73.01 (56.73) is the highest since 1917—78.68 per cent.

4. *Winter Lambing,* 1932.—2,830,000 ewes were reported as either mated or intended to be mated for the winter lambing of 1932. In addition 180,000 ewes were expected to be reserved for spring lambing.

5. *Wool Clip.*—6,404,046 (6,059,246) sheep and lambs were shorn, the total clip including locks, bellies, pieces, &c., being 56,960,732 (53,748,376) lbs., increase 3,212,356lbs. The average weight of fleece for sheep and lambs combined was 8.89 (8.87) and for sheep only 10.75 (10.19) lbs.

6. *Total Wool Production.*—Subject to slight revision of fellmongered wool, it is estimated that the grand total wool production, including the clip and wool fellmongered and wool on local skins exported, was 66,162,687 (63,478,524) lbs., increase 2,684,163lbs., value £2,100,665 (£1,803,849), increase £296,816, the average value per lb. greasy being 7.62 (6.82d.).

II. Cattle.

1. *Numbers.*—All kinds 265,324 (218,985), increase 46,339. Dairying cattle 127,756 (109,672), increase 18,084, classified as follows:—In milk 90,767 (79,805), dry 23,171 (20,406), and heifers springing 13,818 (9,461). In addition there were 14,896 (13,591) other heifers one year and over which are not included in the dairying total, but which are possible additions to the dairying herds.

2. *Butter and Cheese.*—Provisional for 1931-32.—Butter 17,500,000 (12,961,231) lbs., previous record 17,244,389lbs. in 1923-24. Cheese 5,100,000lbs., previous record 3,901,159lbs. in 1930-31. Record quantities were exported.

III. Horses.

185,222 (183,529). This is the first increase since 1921.

IV. Pigs.

109,780 (82,991), being the highest since 1918.

V. Goyder's Line of Rainfall and Livestock.

During the year 1931 the percentage to the total of sheep outside Goyder's line of rainfall increased from 29.87 to 36.12, cattle 25.01 to 28.58, and horses 26.01 to 27.21. The numbers within and without the line for 1931 were: Sheep 4,221,994 and 2,386,987, cattle 189,488 and 75,836, horses 134,825 and 50,397.

VI. Interstate Movement of Stock.

The State gained 52,119 head of cattle, 312,603 sheep, and 2,585 horses by transit of stock between States. The total interstate imports were: Sheep 380,933, cattle 55,418, horses 3,595, and exports: sheep 68,330, cattle 3,299, and horses 1,010. Net export of horses to overseas countries 894.

VII. Slaughtering.

Sheep and lambs 1,378,931 (1,308,976), increase 69,955, including for export 135,386 (20,789); cattle 81,285 (89,585), decrease 8,300; pigs 114,313 (111,307), increase 3,006.

VIII. Value of Pastoral and Dairying Industries.

Provisional for 1931-32: £4,880,000 (£4,422,000), increase £458,000.

1. Livestock as at December 31st, 1931, in Comparison with December 31st, 1930.

Minus sign (—) denotes decrease.

RED COMB EGG ASSOCIATION.

OFFICIAL SINGLE TEST

EGG-LAYING COMPETITION, 1932-33.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens, 243—Section 1, White Leghorns—180 birds. Section 2, Any other Light Breed—6 birds. Section 3, Black Orpington—48 birds. Section 4, any other Heavy Breeds—9 birds.

Twelve Months Test. To start on April 1st, 1932.

SECTION 1—WHITE LEGHORNS.

Competitors.	Address.	Score to Month ending July 31st, 1932.

● New 4-speed Gear Box . . .
● New Stronger Front Cross Member .
● New Heavier Front Spring . .

Greater strength and increased power . . . from these Ford Truck improvements!

THE recent important improvements to the Ford 30 cwt. Truck greatly extend the strength, performance and value of a truck already famous for its power, speed, strength, low price and low running costs.

Power and Speed **. . . . Tremendous pulling power and higher road speeds result from the New 4-speed Gear Box . . . 5 ball and roller bearings in the gear box mean that in all forward speeds the entire drive (from engine to road wheels) is on frictionless bearings . . . A Power Take-off is provided for tipping or for belt-work jobs.**

Added Strength **. . . . comes from the New Heavier 2¼″ Front Spring and the New Stronger Front Cross Member. This re-designed, stronger front suspension will stand up to heaviest work at speed over rough tracks, and relieves radiator, engine, clutch and transmission from all road strains.**

Add to the above improvements the existing Ford advantages of torque-tube drive and radius-rod construction, and you have a 30 cwt. truck unequalled for Australia's strenuous conditions. The Ford is now a *heavy-duty* truck in every detail. Ford design relieves the springs of all driving strain, keeps axles always in alignment, reduces tyre wear and allows positive setting of brakes. Ford economy, too, is remarkable—3d. per ton-mile on a 100-mile-day basis is an average figure.

PAPERS READ AT CONFERENCES.

MY EXPERIENCE DURING TWO MICE PLAGUES.

[By L. B. HUGHES, Goode.]

(Ceduna Conference, July 7th, 1932.)

The first mice plague experienced was that which occurred in 1917, and in my opinion it was far worse than the one experienced this year. This was because farmers were not able to get their wheat away as quickly as they did this year, which speaks well for our efficient railway service and up-to-date harvesting machinery. During the seeding of 1917 I sowed a little of the crop dry, which turned out well, but that which I sowed wet was promptly taken by mice. I stopped seeding until July, and when I started again only sowed about 100 acres as I thought it was getting too late. I should have continued, however, because the late rains which fell made the crop a payable one. I intend sowing later this year in the hope that history will repeat itself. I made a stand for the seed wheat by placing posts in the ground with benzine tins on top, but it was a failure. I then made a mouse-proof yeard, and into this I shot the wheat in bulk, but the mice scratched underneath and got up into the wheat, and to make matters worse weevils made their appearance. This practice cannot be recommended unless the wheat was very dry and could be turned occasionally. The recent plague did not do much damage to the dry-sown areas, but the area drilled in under wet conditions in most cases had to be reseeded.

This year again proved that the plague mice were able to climb so-called "mouse-proof yards." A very efficient stand can be made by putting posts in the ground and placing on top of them half sheets of galvanized flat iron, and laying cross pieces on top of the iron. Reject railway irons are ideal for the latter purpose and can be purchased cheaply from the railways. In the future, any stacks I build of wheat or hay will be built on one of these stands, because mice are prevalent more or less every year on farms and do considerable damage. All feed should be kept out of the reach of mice. They thrive on grass seeds, and grass paddocks should be burnt as early in the year as possible. Seeding should be started early. The ground should be worked so as to make a deep seed bed. Drilling through stubble is even better than sowing after the rain. Poisoning should be carried out early in the year with S.A.P. or phosphorus mixed with pollard and adding a little treacle. Strychnine is best after the rain; mix it with flour. The best trap I have seen is made by sinking a benzine tin in the ground with a drop of water in it. The plague mouse is thirsty and can be easily caught with poison water. All stands should be fairly high, as mice will run up a high post and then jump on to wheat stands. Do not sow after the first rain, and wait till the mice have moved on.

THE VALUE OF SHEEP ON THE FARM IN UPPER NORTHERN AREAS.

[By E. H. HAMPEL, Wilmington.]

Papers read at the Upper North Conference, Black Rock, July 20th, 1932.

Sheep are undoubtedly the most profitable sideline that can be run on the farm. They require little attention and are self-producing, there is no depreciation, and the flock will return a substantial profit each year. In seasons when there is an abundant growth of herbage and grasses sheep will be found very helpful to the farmer by keeping weeds in check before the plough and cultivator which otherwise would be allowed to waste and become a hindrance to the ploughman.

The number of sheep that can be kept on a farm will depend entirely on the amount of grasses and foodstuffs that are available throughout the year, and the greatest care should be taken to avoid overstocking. There should be a plentiful supply of water to which the sheep have free access. Fences should contain six wires and be in reasonable repair.

BREED FOR THE DISTRICT.

In my experience, I have found the Merino ewe mated with the Merino ram to be the soundest and most profitable proposition. Purchase, if possible, ewes between two and three years of age and only of a good standard, strong constitution, large frame, clean points, and fairly free from wrinkles. They should carry an even fleece of preferably strong wool, showing plenty of character.

For every 100 ewes three rams will be required, which should be well selected. It must be remembered that inferior rams will soon deteriorate the flock, and if the most is to be made out of sheep, then they should be maintained at the highest possible standard. This can only be done by careful selection of the rams, and rigid culling of the ewes from year to year.

I am definitely of the opinion that a farmer should be a breeder of sheep and not a dealer; this will mean that the best ewe lambs are selected each year, and retained for breeding purposes, thus taking the place of those passed out.

MANAGEMENT.

Like all other livestock, sheep require proper management to be most profitable. Dipping is important and should be carried out from six to eight weeks after shearing. Generally speaking, the middle of November will be found the most suitable time to join the rams; this ensures an April-May lambing, which is an ideal time of the year for such purpose. Crutching is very necessary and should be done preferably with machines in the beginning of March. The sheep should be handled very carefully during this operation, which, if thoroughly carried out, will reduce the blowfly pest to a minimum.

Lambing.—A paddock should be reserved for this purpose. Horses and cattle must not be allowed to graze with the ewes whilst lambing, and whenever an opportunity offers, take a walk around the sheep to see that all is well. Dogs are best left at home unless they are well trained.

Lamb Marking.—This may be done at the end of May or the beginning of June. If possible, avoid cold and frosty weather; also see that the lambs are returned to their mothers and back in the paddock well before sundown. Thorough cleanliness should be observed during this operation. Kerosene and olive oil applied to the wounds is most helpful. It is advisable either to brand or number the lambs whilst this work is in progress.

Shearing.—Everyone will agree that September is the most suitable month for shearing, and if a depot shed is available within a reasonable distance, the sheep should be taken there to be shorn, so that the wool will be properly classed and put up in the most attractive style for the buyers, whereby the highest possible price may be obtained. Failing this, they may be shorn on the farm in some convenient shed, which must be free from dirt, chaff, &c. Under these circumstances do not class the wool. Take off any pieces that may be wet or soiled around the breech, placing these on a rack to dry. The fleece can then be rolled and placed in the bale.

Bellies and lambs' wool should be baled separately. Place the mark on each bale and number them, using stencil plates, and when consigning, advise the brokers to reclass, for which a small charge is made. Then the clip will be classed by experts and interlotted, thus gaining the highest price possible for it.

Culling and Casting.—Culling for wool is best done on the shearing-board, and all sheep having yellow, hairy, unattractive and short stapled fleeces should be raddled off. Casting for age and constitution is also necessary and can be most conveniently carried out in the branding race, after which all the raddled sheep should have a number placed on them and the whole flock branded.

Now that so much has been said for selection and management, what may one reasonably expect from 100 ewes, even at present low prices for lambs and wool? The increase may be safely estimated at 80 per cent. and losses in the ewes at 5 per cent. Therefore, let it be assumed that 95 ewes are shorn, averaging between 7lbs. and 8lbs. of fleece wool and about 3lbs. of oddments. The lambs will easily average 3lbs. of wool.

The rams will pay for themselves during their service by the wool they produce in that time, and so need not be mentioned in the following summarised statement of income and expenditure, in which are shown the gross profits of one year and the necessary deductions.

The prices set down for wool and lambs are those obtained during last year, and are as nearly as possible an average that was received.

Gross Profits.

	£	*s.*	*d.*
700lbs. fleece wool at 8d. per lb.	23	6	8
300lbs. oddments at 4d. per lb.	5	0	0
240lbs. lambs' wool at 3d. per lb.	3	0	0
80 lambs at 10s. each	40	0	0
Total gross profits	£71	6	8

Expenditure.

	£	*s.*	*d.*
Warehousing commission and freight on wool	6	7	0
Commission on lambs	2	0	0
Shearing	4	0	0
Dipping	0	16	8
Crutching	1	0	0
Woolpacks, branding oil, &c.	0	15	0
Total expenditure	£14	18	8
Showing a net return of	56	8	0
	£71	6	8

Or the equivalent of 11s. 3d. per ewe.

PIG BREEDING AND BACON CURING.

[By B. J. G. Schuppan, Wilmington.]

In my opinion sufficient attention is not paid to the breeding of pigs which entirely differ in type and quality, and each breed should be used for the purpose for which it is best suited. From a curing point of view it is quite true that any pig will make bacon or ham, yet it must not be forgotten that every pig is not a good baconer or suitable for curing.

Breeders and curers should lay down a definite standard, setting out the advantages or otherwise of the various breeds. One can breed exactly what is required from the breeds of pigs from which it is possible to make a selection, including the Berkshire, Mid-York, or Poland China and Tamworth. Each of these breeds has been highly recommended by the curers, yet none of these breeds is perfect, and a great improvement could be made by devoting a little time and attention to breeding.

The Berkshire is an ideal pig, one which we regard as the best from a curing point of view, yet it carries rather too much fat in proportion to lean, and is slow in maturing. Further, in many cases the sows are shy breeders. Many instances are on record where three or four big litters have been produced and then the sow ceased breeding. This appears to happen in the Berkshire more than in any other breed. This drawback could be easily overcome by the introduction of new blood.

For a curing pig I favor a well-bred Berkshire sow mated with a Mid-York boar. This progeny should be crossed with a Poland China and then mated back to the Berkshire boar, and from this offspring the breeders can be selected. This type of pig will prove of the highest quality. Nice shapely pigs, very similar to the Berkshire but longer and deeper in the body, fine hair, well proportioned with fat and lean, very good curers, meat not too soft and flabby, which is very often the case with many of the other breeds, which are meant for pork, and not for ham and bacon.

If factories would pay more attention as to the class of pig suitable for the various types of meat, there would be a ready demand, and better prices obtained for the produce. As the factories are mainly working on light weights—from 80lbs. to about 120lbs. for baconers—it means that feeding has to be forced to place the pigs in the market at four to five months. Such meat is immature, and it is impossible to cure good quality stuff from an unsuitable article. One cannot obtain good beef from a calf of that age, and the same applies to pigs.

In curing, it is necessary to avoid shrinkage and loss of weight, which would be very considerable in a young pig. This can only be overcome by feeding gradually and allowing the pigs to mature at about 200lbs. or more. From a pig of this weight one should be able to cure meat which would keep at least nine months, after which period another pig could be treated. There are three months of the year during which it is possible to cure successfully, and if this plan was adopted the house would be supplied with ham and bacon all the year round and so result in a great saving in the butcher's bills. Now that pigs are so cheap, it would be more economical to kill and cure as much as possible and keep the profit on the farm. If all producers were to follow on these lines, it would help to strengthen the demand and firm the prices of the market. If one has more than his own requirements, it is not difficult to find a ready market for it. Where the pigs would only realise from 4d. to 6d. per lb. through the market, it would be possible to obtain at least from 8d. to 10d. for the cured meat.

If it is intended to adopt this latter plan, care should be taken to class and joint the meat. A pig contains at least six or seven different "cuts" of meat, and each is valued at a different price—some up to 1s. 6d. per pound when prepared, yet when used as pork or sold in the market one has to be satisfied with 5d. per lb.

In jointing a pig, cut down the centre of the back with a sharp knife, then cut down each side of the ribs, in the inside. The pig would then be in halves, with the backbone on one side. Run the knife along the other side of the backbone and the sides will be ready for jointing. Place on a block and carefully remove the kidney fat. Next, remove the lean strip of meat above the ribs along the back. This can be done by starting at the shoulder and working towards the ham. It may be necessary to use the knife along the back to separate the meat from the fat. Now remove the ribs by carefully drawing a sharp knife under them. Start at the shoulder and gradually work backwards until the short ribs are reached, which should be far enough to run out. The ham of a neat shape should then be removed. After this, cut the meat straight through behind the shoulder. This can be made into shoulder ham or it may be jointed. The sides of the bacon will now have a strip of fat along one side which must be removed. This strip of fat is used for lard.

The meat is now jointed and ready for salting and curing. Rub each piece separately according to size. The heavier pieces—hams and shoulders—should receive a heavier dressing of salt. Store the meat to allow it to drain for at least 24 hours. By this time most of the blood will have drained out and the meat will not stain the brine. When preparing the brine, do as before mentioned: keep the hams and shoulders separate. For these the strength of the brine should be about 1¾lbs. of salt to every 1gall. of water, with the addition of ¼lb. of saltpetre to every 10galls. of water. For the bacon and remainder of meat, use 1¼lbs. of salt with the same quantity of saltpetre. Boil the brine, but care must be taken that the brine is thoroughly cool, and it should be put outside overnight. The time of curing will depend on the size and weight of meat.

A ham of 15lbs. will take at least four weeks, 20lbs. five weeks, 25lbs. to 30lbs. at least six weeks to salt. The bacon will require two weeks' curing. The cured meat should then be placed in a tub of fresh water for at least 12 hours to soak and then hung to drain for four or five days, when it should be ready for smoking. This should be done under as even a temperature as possible. Bring the meat to a sweat, but do not allow it to drip. About two days' smoking should be sufficient, providing the heat has been regular. A better plan if it can be done is to smoke it for one day, then allow three or four days to elapse and smoke for another day. The meat should then be hung in a dry safe place until required for use.

THE USE OF PRODUCER (OR CHARCOAL) GAS FUEL FOR FARM TRACTORS.

[L. M. W. JUDELL, B.Sc., F.S.A.S.M.E., Jamestown.]

In this paper it is proposed to give a brief survey of the adaptation of the use of producer gas fuel for use in farm tractors, without any attempt to enter into the details of design of apparatus, and with as few technicalities as possible. During the past two years the wheatgrowing farmer has been forced by low wheat prices to do his utmost to lower his costs of production. Power is certainly only one factor in the schedule of costs, but it is an important one, and offers considerable scope for effecting economies. About 4,000 tractors are used on wheat farms in South Australia; these have practically all been imported, and the fuel, which also comes from abroad, costs annually somewhere about six hundred thousand pounds.

HISTORICAL.

Producer gas, or suction or charcoal gas as it is sometimes called, is not a new discovery. It was used a hundred years ago in France, Germany, and Belgium as the base for illuminating gas. The general use of internal combustion engines, primarily using coal gas, led to the utilisation on a large scale of producer gas as a cheaper fuel in all parts of the world from about 1880 onwards. In Australia this gas has been used very widely for smaller power units, in flour mills, pumping plants, country town electric light installations, mines, and mills, &c. In France the lack of domestic supplies of liquid fuel or good coal led to the development by French engineers of serviceable gas producers, to enable wood charcoal to be used as a fuel for motor trucks. In 1927 there were several thousand motor trucks in France operating with producer gas made from charcoal; the French Government encouraged the introduction and use of producer gas for commercial motor vehicles.

In 1927 the Commonwealth Development and Migration Commission deputed a Mechanical Transport Committee to investigate the possibilities of the use of producer gas for motor trucks in Australia. Through the courtesy of the Secretary of the Commonwealth Department of Transport (Melbourne), I have been supplied with copies of the detailed reports of extensive trials in France and Australia of this gas used in various makes of motor vehicles. Briefly summarised, these reports state that the trials generally were satisfactory, and led to great economies in fuel costs. Coming nearer home, early in 1931 Messrs. Smith & Son, agricultural implement makers, Ardrossan, made and placed on the market a gas producer for use with tractors; several of these were fitted to Holt tractors, and were operated in various parts of the State, particularly in the Appila district, where some trials were held. The gas producer used charcoal fuel, and gave fair results; the reasons why they did not come into more general use were probably excessive weight, inconvenient location of the producer on the tractor, and a fairly high first cost. It must be remembered that Messrs. Smith and Son were the pioneers of the introduction of producer gas fuel for farm tractors in this State, that their producers were strongly made, and constituted a genuine and creditable attempt to offer to the farmer an opportunity to lower his tractor fuel costs.

The best practical results in the adaptation of producer gas as a fuel for farm tractors in South Australia, and probably in the Commonwealth, I consider have been obtained by Messrs. J. and W. F. Slattery on their farms, "Moorlands," near Jamestown. Messrs. Slattery Brothers sow about 1,600 acres of wheat annually and use three tractors. During the winter of 1931 they experimented with their own design of gas producer, and by November had evolved a producer which gave satisfactory results in their cultivating operations on their farm and in a trial conducted by the South Australian Committee, consisting of Messrs. J. P. Burnside, T. J. Bromley, M. Watson, W. A. Hargreaves, and W. L. Summers. Messrs. Slattery Brothers used two 2-ton Holt tractors operating on producer gas (charcoal) for their seeding operations, and to date have cultivated over 3,300 acres using this gas as fuel. They are now ploughing, using the same fuel, and report that a 2-ton Holt tractor is pulling a 7-furrow mould board plough quite satisfactorily. A feature of Messrs. Slattery Brothers' operations is that the gas producer is carried on the combine or plough, and not on the tractor. As regards their fuel costs, they combined in 1,600 acres at a cost for charcoal of £8, which works out at slightly over one penny per acre. The engines of the tractors working with this fuel are in first-class order, and show no signs of unusual wear or depreciation in any respect. There is no dilution of crank case lubricating oil through unconsumed liquid fuel, and Messrs. Slattery Brothers have found an extraordinary reduction in the quantity of lubricating oil necessary; they used one tractor to cultivate 600 acres with a consumption of only one quart of cylinder oil, and the drainage from the crank case at the end of that run was discolored, but still retained a good deal of lubricating quality.

NATURE OF PRODUCER GAS.

The gas is made by passing air and steam through a bed of incandescent (red hot) carbonaceous fuel. By reason of its accessibility, cheapness, and freedom from volatile matter, charcoal is the ideal material for making this gas for tractor purposes. When air is brought into contact with red-hot charcoal, what we call combustion takes place, heat is evolved, and the gas carbon dioxide is formed; this is a colorless, odorless, inert, incombustible gas. The carbon dioxide gas in passing through the bed of red-hot charcoal is changed into another gas, carbon monoxide, which has quite different properties to the dioxide; it is colorless, has a faint odor, is combustible, and when mixed with a certain proportion of air is explosive. Carbon monoxide is also poisonous, and care should be taken not to inhale producer gas. Steam or water vapor, in its reaction with the red-hot charcoal, forms hydrogen gas, and with air forms an explosive mixture. The formation of carbon monoxide and the decomposition of steam are both chemical reactions which absorb heat; this is fortunate, in that it prevents the development of excessively high temperatures in the gas producer furnace. Another chemical reaction which should not take place in the producer furnace, but sometimes does, is the formation of clinker. This is due to the presence, as an impurity in the charcoal, of earthy matter, which at the high temperature reacts with the potash and soda salts in the charcoal ash to form a fusible slag or clinker. The obvious way to avoid this troublesome clinker is to use only clean, retort or kiln burned charcoal, which is usually free from earthy matter. Producer gas, then, is a mixture of carbon monoxide (30 per cent.), hydrogen (8 to 10 per cent.), nitrogen (48 per cent.) from the atmosphere, which passes through the apparatus unaltered, some carbon dioxide (6 per cent.), and water vapor; the figures given are approximate only. It is a low-grade fuel gas, which possesses only about one-fifth of the calorific or energy producing effect of average coal illuminating gas.

USE OF PRODUCER GAS.

The problem of utilising efficiently this low-grade gas in a tractor engine designed for the use of comparatively high-grade liquid fuel is not an easy one to solve. There are certain difficulties which can be overcome, and other inherent disabilities which cannot be removed; it is desirable that these should be understood. It is desirable that the gas should be delivered to the engine cylinders as cool, clean, and dry as possible. As all gases expand in direct proportion to the temperature, when heated, it is evident that the cooler the gas, the denser it will be and the more energy units it will be capable of giving out per unit of volume. The necessity for cleaning out, by means of efficient scrubbers, all solid matter, such as dust, and all liquid matter which would damage or interfere with the cylinders, pistons, valves, and spark plugs, is self evident, and the drier the gas can be made the less dilution there will be by water vapor. It is not possible, by means at present known, to develop, with producer gas, the same power in a tractor engine designed for liquid fuel as that developed by the engine when using liquid fuel. That could hardly be expected. The loss of power when using producer gas in such an engine under most favorable conditions would be about 15 to 20 per cent. To obtain the best results with the use of producer gas as fuel, the engine should be specially designed. For instance, the compression of the mixture just prior to explosion should be not less than about 80lbs. per square inch. The power developed by an engine is calculated from the formula—

$$\text{H.P.} = \frac{\text{P.} \times \text{L.} \times \text{A.} \times \text{N.}}{33{,}000}$$

where P. is the mean pressure in pounds per square inch; L. the length of stroke in feet; A. the area of the piston in square inches; and N. the number of explosions per minute. The product must be multiplied by the number of cylinders in the engine.

Keeping this formula in mind, it is interesting to see how Messrs. Slattery Brothers have got the best result out of their Holt tractors when using producer gas as fuel. The mean pressure P. is certainly lower for producer gas than with kerosene or petrol, but this loss was minimised by increasing the compression ratio by making the pistons ⅜ of an inch longer and raising the compression to about 90lbs. per square inch; the length L. is the same, depending on the crank shaft; the sectional area A. is the same; the speed factor N. was increased from 900/1,000 to 1,300/1,400 revolutions per minute. At the same time the gear ratio was altered so that the travelling speed of the tractor remained about the same as in the original design. In other words, the gear ratio was stepped down and the original tractive effort practically maintained at about the original speed. These facts can only be generalised, as no dynamometer tests were made, but the results were borne out in actual work on the farm, where over 3,300 acres have been cultivated and tilled.

The relative merits of wood and charcoal as the fuel source for producer gas are occasionally debated, but for use with tractors I cannot see any advantage in using the producer as a charcoal retort and passing a large volume of volatilised water and other products of distillation through the apparatus and to the engine, as would happen in the usual up draught design of producer. The time taken to light up and start the tractor when using charcoal and gas is generally about 7 to 10 minutes with Messrs. Slattery Bros.' outfits. The producer holds three bags of charcoal, sufficient to run for about 5 hours without refuelling. No fan is used to assist the draught when starting; the top lid is removed, and the natural draught through the ashpit door up through the column of fuel is sufficient to get the fire well alight. The engine is started with a small amount of petrol and run for a few minutes to suck the gas through the scrubbers and to the engine through the connecting hose.

CONCLUSION.

The use of producer gas with tractors can never be as simple and fool-proof as is liquid fuel and it is doubtful if this gas will be very generally used on wheat farms. A certain amount of aptitude and understanding of machinery is necessary in order to make a success of the use of this cheaper fuel, but I feel certain that for such men there is a great field in South Australia for growing wheat on the large areas of light plain country at a lower cost than can be done anywhere else in the world. With low fuel costs, large areas can be covered with tractors and the problem of providing feed and water for horses in dry years is eliminated. This idea opens up a very interesting subject which time and space will not allow me to deal with here. The use of cheap, locally produced fuel for tractors on wheat farms is very well worth the attention of farmers or investors, particularly those who are of a mechanical turn of mind.

SHEEP SUITABLE FOR FARMING DISTRICTS OF SOUTH AUSTRALIA.

[By R. Elliot, Kulkawirra.]

(*Murray Lands, Karoonda, August 2nd*, 1932.)

Coming as I do from the edge of the western plains of Victoria, where some of the best wool in the world is grown, and having got the best part of my living from sheep for a good number of years, I am inclined to agree with the writer of an article which I read in the *Advertiser* some time ago, that there is grave danger of the raising of fat lambs spoiling the quality of farm-grown wool—few of the breeds of sires used in the production of fat lambs producing a desirable quality of wool—and there is such a mixed variety of sires being used that there is not likely to be any uniformity in the production of either lambs or wool, and we cannot afford to neglect either, there is too much risk in specialising in lambs, for judging by last year's happenings it is quite possible to glut the market for lambs, a large number of lambs from last season still being in cold storage very late in the year.

Wool is very low in price at the present time, but it will gradually right itself to a certain extent with more normal economic conditions. South Australians can do what has been done in other places to a certain extent: breed sheep that will give a good lamb, and also produce a good fleece of good quality wool.

THE POLWARTH.

In New Zealand the English Leicester crossed with the Merino has given good results and produced a large number of the best Canterbury lambs. This cross also produces a good quality wool, but the sheep that more nearly approaches the class for the Mallee is the Polwarth. This bred originated some 50 years ago in the Western District of Victoria, and is really a standardised comeback, and was originally bred by Messrs. Dennis Bros. and Mr. Wittenhall, all breeders of Merino sheep. The object which they had in view was to breed a class of sheep that would produce the best return in £ s. d. per acre. That they were satisfied with the results is evidenced by the fact that they and their sons have continued to breed up these sheep

to the present time, and that other Merino sheep-breeders are now turning to Polwarths in preference to Merinos. Even the chairman of the Sheep-breeders Association, Mr. Edwin Currie, of Lismore, whom I think holds the record for a price paid for a Merino ram for Australia—3,000 guineas—now has a stud of Polwarth sheep. The name Polwarth was given to these sheep in 1919 at a meeting of breeders, and now there are 52 studs and flock-book flocks registered, only one of which is in South Australia—that of Mr. Sullivan, of Bordertown. The wool from these sheep always brings a price very little, if any, below that of the Merino, and the sheep cut very nearly the same weight of wool with less off the bellies and pieces, breed a much better lamb, produce a much better carcass of mutton, the ewes are good mothers, and rear their young well. There should be no reason why sheep of this class cannot be bred even more successfully in the Mallee than in Victoria, for the South Australian Merino is a much better sheep, particularly in point of size, than the Victorian Merino.

The origin of the Polwarth sheep is the Lincoln-Merino cross, the Polwarth being three-quarter bred Merino. These sheep were bred from selected sheep on both sides.

The easiest way to develop a flock of this type of sheep would be to use Corriedale rams on good class Merino ewes, the Corriedale being a standardised Lincoln-Merino half-breed. The main trouble in this district at the present time is to procure an even flock of ewes, and farmers will have to breed the ewes, culling as heavily as circumstances will permit. I have been breeding on the lines mentioned for the past three years, and have now mated ewes with Victorian Polwarth rams, and have the first drop of lambs by these rams running with the ewes. We also bought 105 Victorian-bred Polwarth ewes, which also have their first drop of lambs for this district at foot now. The rams which were bought in the wool were rather smaller than I expected, but were very short-legged and solid when shorn, very like the Southdown in conformation, with neither horns nor wrinkles. I anticipate that the locally-grown Polwarths will grow to a much larger size than those in the colder climate of Victoria. Lambs by Corriedale rams have weights up to 50lbs. at five months old, and in the Victorian Mallee Polwarth lambs have been credited with attaining the weight of 45lbs. to 50lbs. at 13 weeks old. One of the advantages claimed by breeders of these sheep is that the wool is so even in quality that the whole clip can be put up in one or two classes. This depends on the care of the breeder in culling unsuitable sheep, but registered flocks have to be subject to regular inspection by an expert.

HORSE BREEDING.

[By J. R. McKenzie, Pinnaroo.]

(*Pinnaroo Line Conference, Jabuk, August 4th,* 1932.)

Horse breeding is a very interesting and at the present time a very remunerative occupation. Unfortunately, the farmer does not always pay enough attention to the type of horse that he is breeding, although farmers are not to blame for all this. There has been such a serious falling off in horse breeding the last 10 or 12 years that stud breeders have not had any sale for their stallions except the very best, and the rest have all been gelded, hence now that there has been a revival in horse breeding, there are not enough good young stallions to meet requirements, and farmers are inclined to use any stallion without thought of type or breeding.

When a breeder sets out to breed horses or form a stud, he should have a certain standard in view and aim to produce a certain type of horse. To do this—if it is impossible to secure mares possessing the desired qualities—the breeder should use a stallion bearing as nearly as possible the required characteristics. By doing this for several generations it will be possible to gradually grade up to the required type.

Some of the leading breeders adopt line breeding, and this is the quickest way to fix a standard. Line breeding calls for a good deal of inbreeding. The inbreeding of stock possessing certain desirable qualities tends to intensify those qualities, but it also tends to bring out undesirable characters that may have existed in past generations. Therefore, to fix a standard, the stud breeder must be ever rigorously culling his stock, and using only those that conform to the required standard.

As the foregoing is not always applicable to the average farmer unless he is going in for stud breeding, an outline of some of the principles a farmer should follow when breeding horses for farm purposes will prove of interest. The farmer should not endeavor to breed from any or every mare he has, but select some of the best for the purpose. There are several qualities he should pay attention to, such as the disposition of the mare, her working qualities, and a mare that is naturally a good doer.

In the choice of a stallion the farmer often has to use whatever is available, but if he can choose between several stallions he should endeavor to select one most suited to his mares. If a mare has a certain fault he should try and avoid that fault in the stallion, and if there are certain characteristics he desires, he should then try and secure the services of a stallion possessing them. It must always be remembered that the better the parents are bred, the more uniform will the progeny be, and uniformity is a very desirable quality in a team of horses. Only stallions that are free from hereditary unsoundness should be used.

Having selected the mares and the stallion to be used, they should be mated in the months of September, October, and November. October is the best month for mating in this district, because the mare will foal in September, when the weather is warm and there is plenty of greenfeed available. Four years of age is the best time to start a mare breeding, although mares have started to breed successfully at a much younger age. "Dunure Footprint"—the most famous stallion in the history of the Clydesdale breed—was foaled when his dam was only 2 years and 10 months old. If one has valuable brood mares, the practice of breeding from them at 2 years can be adopted, but this is not advisable from ordinary farm mares.

CARE OF BROOD MARE.

It is a good practice, when a mare has been served, to leave her out of the team for a few days, and keep her as quiet as possible. When the mare is in foal she can be used for ordinary farm work. The brood mare should not be regarded as one of the regular team, but more as a spare horse. By doing this, it will be possible to get a lot of work from her, and not hurt her. Avoid heavy wagon work, if possible, and never use the mare to breech the wagon or dray. Breeching work is very harmful to a mare in foal.

When the brood mare is in the team, work her on the near side, and, if there is more than one brood mare, they should always be worked together. Care should be taken at gates, and if the gate is at all narrow the brood mare should be taken through separately. A brood mare should on no account be struck with a whip. The mare will be able to do ordinary farm work up to within about a month of foaling, and then kept apart from the rest of the team. When the mare is near foaling she can be kept in a small paddock near the homestead, where she can be watched. A little help at foaling is often very beneficial to both mare and foal. Many foals are lost or injured through no one being at hand when the foal is born.

The mare and foal should not be turned out with the rest of the horses until the foal is at least one month old, and then care must be taken, because the other horses become excited, and usually chase the foal. If it is possible to avoid it, the mare should not be worked while she is suckling the foal, but if she has to be worked, shut up the foal in a small yard. If the mare comes in very hot, allow her to cool before permitting the foal to suck. Usually by the time the team have walked home from the paddock she will have cooled sufficiently. Sucking the mare when she is overheated will cause the foal to scour. Wean the foal at six months old, especially if she is again in foal. If, however, the latter is not the case, and she is not required for work, the foal can be left on the mare longer. On no account must a foal be left on the mare the following season, when the mare is to be put to the stud again, because it is very difficult to get a mare in foal with a yearling sucking her.

Handle the foal as soon as it is born. If the foals learn to tie up, and are handled frequently about the head and legs, they never require any breaking in when they grow up, and should they meet with any accidents—as foals or young horses often do—they are always easy to handle. Inspire confidence in them, and they will never forget it as they become older..

Australian farmers are realising that, by producing their own farm power, and growing the fodder on the farm to feed them—thus using for home consumption what would otherwise be put on to an already over-supplied market—they are not only helping themselves, but are helping Australia out of her troubles as well. When the farmer is prosperous, everybody is prosperous. The slogan, ''Breed Horses for Prosperity,'' is a good one.

SHEEP, WOOL, AND WOOLCLASSING.

[By T. M. Rice, Pinnaroo.]

(Pinnaroo Line Conference, Jabuk, August 4th.)

Historical.

The first sheep to be imported to Australia were the Cape Fat Tail, about 1788. These sheep were of a variety of colors, covered with coarse, frizzled hair, and having large, fat tails, weighing up to as much as 10lbs.; hence their name. Two or three years later a poor type of sheep was imported from India. The Spanish Merino, which has made Australia the finest wool-producing country in the world, was imported by Captain Waterhouse about 1789 from South Africa. On reaching Botany Bay Captain McArthur offered him 15 guineas a head for the shipment (29 sheep). This offer was refused, and the Colonial authorities instructed Waterhouse to distribute the sheep amongst several settlers. McArthur managed to secure three rams and five ewes. He noticed that the sheep flourished in their new home, the wool becoming heavier, softer, and finer. In 1803 a sample of wool was sent to England, and valued at 6s. per lb. He saw great possibilities for the industry, so about the end of 1803 (his flock then totalled 4,000 sheep) he went to England, and endeavored to float a company, with the object of extending operations. His scheme was ridiculed by the English Government and by the capitalists; they considered that sheep would not live on the grasses and herbage in Australia, and that sowing English grasses would make the undertaking too expensive. However, he was able to purchase a few sheep from the King's stud, and, after a few more years in Australia, was noticed to be making such a success of his venture that other keen business men went in for sheep raising. Captain McArthur well deserves the title of the ''Pioneer of the Sheep and Wool Industry of Australia.''

The increase in numbers of sheep in Australia has been remarkable since 1792. That year the total was 105; in 1805 there were about 11,000; by 1842 the number had increased to over 6¼ millions. In the 1820's and 30's everyone seemed to be going in for sheep, and it was overdone. The boom burst in 1829. Sheep that had been worth up to £3 a head five or six years before were only bringing 2s. or 3s. per head. Boiling down was started, and continued for five or six years. Many squatters became bankrupt, and many were only saved by killing and boiling down their entire flocks. By 1850 conditions started to improve, and continued to do so at a more or less steady rate, so that by 1909 there were about 46 million sheep in the Commonwealth. The present total is, roughly, 110 millions.

THE FARMER'S REQUIREMENTS.

The aim of the average farmer is to produce a good lamb, and, at the same time, obtain as much as possible for the wool from the ewes. The Merino ewe will eclipse either the crossbred or the pure bred English ewes for wool. On the other hand, the half bred or crossbred ewe will rear a better lamb than the Merino in a much shorter time.

The average mallee farmer should have a flock of ewes that will cut a reasonably fine quality wool, and mate them in such a manner that, should it be impossible to dispose of all the lambs as lambs, they will also cut fairly fine wool.

SHEARING.

Shearing is a busy time. However, the work can be done expeditiously if the farmer has everything in readiness for the shearers. On many farms a shearing shed is not provided, or, if there is one, it is used for other purposes ten months out of twelve. As shearing time approaches the shed should be thoroughly cleaned out. All straw, chaff, binder strings, birds' nests, &c., should be removed. The gratings and yards should be put in good order; also the gates and shearing board. A suitable table should be provided for skirting and rolling the wool, as well as bins for the accommodation of the wool. Small bins are a mistake, and should be avoided. Farmers who have their own plants should have on hand a reasonable supply of duplicates, emery paper, oil, &c., and some suitable disinfectant for dressing cuts and possibly fly-blown sheep will be needed. Sheep should be drafted into suitable lines, *e.g.*, hoggets, wethers, ewes, etc., before shearing starts. This enables classing to be done more efficiently.

As the sheep are shorn, the fleeces are picked up and spread on the rolling table by the wool picker. The correct way to pick up the fleece is to stand at the neck end, and, reaching over, grasp the breech in both hands and draw the fleece towards you in folds until it can be lifted in the arms. On reaching the table the fleece is thrown towards the end away from the picker, always remembering to hold the breech until the fleece is at rest. Throwing the fleece is a job which requires a certain amount of practice. Fleeces will not stand much of a jerk, particularly Merinos, or they will break and land on the table in a tangled mass.

When the fleeces are thrown on the table they are skirted and rolled ready for classing. Skirting is perhaps the most important part of the work in the wool room. Its object is to remove all wool from the fleece that is detrimental in any way to the average wool in that fleece, thereby increasing its value. If the wool is free from burrs only a light skirt is necessary. Remove only the sweaty locks from behind the shoulder and round the breech, the short, hairy wool on the leg extremities, and the heavy-conditioned neck wool. If sand is present to any extent in the backs it will pay to remove them. If there is a moderate number of burrs, and these can be removed by taking a fairly deep skirt, it is advisable to do so; but if the fleece is burry all over no good purpose will be served by doing more than a little skirt. When skirting is finished the fleece should be rolled as follows:—Fold in the neck, then fold the fleece in thirds from one side to the other, and roll from the breech to the shoulder. This should leave the best wool of the fleece—viz., the shoulder wool—on the outside. As the fleeces are rolled they should be set aside, the first twenty or thirty, at any rate, to enable the classer to set a standard for the lines he may intend making, then classed into their respective bins.

There are five important principles to be taken into consideration in classing wool, namely, *length*, *strength*, *quality*, *color*, and *condition*. Lines should be made as even as possible, remembering each of these principles. *Length* explains itself. *Strength*, or *soundness*, is also more or less self-explanatory. There are three degrees of soundness, viz., sound, unsound, and tender. Lines of even strength must be made, or a loss of competition of buyers will result. Some manufacturers cannot handle tender wool economically. *Quality*, *i.e.*, spinning quality, refers to the fineness or coarseness of the wool fibre. Values, to a large extent, are based on quality. The terms used to describe quality are known as "counts"; for example, 60's, 56's, 36's, &c. When wool is termed a 60's quality it is meant that 1lb. of scoured top will produce 60 hanks of yarn each 560yds. long. A pound of 70's scoured top will produce approximately 22 miles of spun yarn. *Color*, or brightness, is a term which explains itself. *Condition* refers to the amount of grease or foreign matter in the wool. Lines of even condition are essential if best results are to be obtained.

Locks, Bellies, and Pieces.—On the average farm there will be no more than sufficient to make a line of each of these. Do not put them into a bale all mixed together. The pizzle stains should be removed from the wether bellies and dried before baling or bagging; also any other wet wool. The bales and packages should be packed as neatly as possible and branded with stencils on both top and front.

OUR CROP COMPETITIONS.

[By R. C. JACOB, Geranium.]

(*Pinnaroo Line Conference, Jabuk, August 4th.*)

By introducing this subject to the deliberations of the Conference, it is hoped that a good discussion will be created on the matter, that both profit and pleasure may be the result. The writing of the paper has been prompted by the articles appearing in recent numbers of the *Agricultural Journal*, the "Cost of Growing Wheat on a Mallee Farm," and the review of the factors pointing to the success of the winning and leading crops in the County of Chandos and adjoining Mallee Competitions for the last few years, which are directly connected with our district, and so vitally concern our ultimate success.

The one proves the cost of growing wheat on standard lines, and the other points to the means of attaining or exceeding those results. Wheat Crop Competitions have been carried out in this district for a number of years, and the system has developed and been improved on until it has grown to be the largest competition in the State—if not in the Commonwealth—showing that an increasing number of farmers realise their value, but it is only in recent years that the details have been tabulated and analysed.

A greater number of entries would increase the value of those analyses tremendously by showing a truer average result. With a larger number of entries, the committee could either accept a lower entrance fee or give a greater number of more valuable trophies. The Competition would then grow both more valuable as a guide to raising the general average of production in the district and in interest to those concerned in it.

Owing to the forced curtailment in Government expenditure, the subsidy was withdrawn, and experimental work curtailed, so that it remains with farmers themselves to carry on and solve their problems in this respect; but they know they can rely on the Department of Agriculture for all the help that is possible. Some farmers even advocated further curtailment of Government expenditure in the Department of Agriculture but strangely we do not see these farmers figure in any attempt to fill the gap in this connection.

There may be some farmers who grow better crops than any in the competitions, or even average more than the average of the competition plots. If so, it is to be regretted that they cannot be persuaded to enter, and so have the secret of their better methods made available for the benefit of their less fortunate farmers, and thereby help to raise the average of production.

It may be argued that farmers do not need competitions as an incentive to increased production, but is there a farm that has yet reached the limit of its production, or can it be stated what the limit is? It is certain that the average in each distirct is well below the average of the best farmers in that district, and a well supported and organised competition would yield figures over a period of years that would point the way to definite results being obtained to raise that average.

It cannot be doubted that in this particular locality there has been a distinct improvement in the seed sown generally and a reduction in the amount of disease since the inception of the Competition. It must be admitted, therefore, that Competitions have an influence for good, and are worth while, but to obtain the full benefit from them, they must be improved, because stagnation leads to decay. That can be achieved by the committee, and farmers generally tackling the job with an open mind, and accepting both criticism and advice.

SUGGESTED ALTERATIONS.

In the first place, the basis of the Competition is a 50-acre plot of wheat, not confined to any definite shape, but must be marked out by flag or binder cut. It must contain no more than three varieties and must be in one piece, except under special circumstances. The class of land is not taken into consideration. This question is governed by the State Crop Competition for which the Royal Agricultural and Horticultural Society offers a valuable trophy. It is contended that if the trophy were for the whole farm, the result would be more satisfactory. Others hold the view that the area should be reduced, because the results would be more accurate.

From the point of view of improving average production it would be a great advantage if sufficient entries could be obtained to divide the Competition into two groups: say (1) first-class land; (2) second class, and even further by dividing the second into (*a*) crops grown on a fallow system, (*b*) crops grown on a rotation system, without fallow, because it is in the second class and poorer land that the weaknesses show up in the averages.

Most farmers can, by following approved methods, grow good crops on their best land in good seasons, and in some cases the production is nearing the limit according to the rainfall, which cannot be controlled, but nobody has yet definitely evolved a system to bring up the second class land to anything near the rainfall limit. It is not possible to control the rainfall, although the best use can be made of what falls. The condition of the land can be controlled and improved by correct methods. This, of course, is wrapped up with the question of drift. It is generally agreed that wheat cannot be grown profitably without fallow, and it is also evident that on some land fallowing cannot be continued indefinitely without serious results. If every farmer at the Conference would support systematically a Competition on these lines, it would not cost very much to organise, and the details would be of more value and lead to more definite results than any experiments carried out in one particular spot—provided records were well kept.

JUDGING.

Judging could be simplified by special committees being appointed in each district to draft out the best crops for judging. This question of judging is one that always comes in for criticism after a Competition of any sort, and while one has every confidence in the judge, it is realised that he may subconsciously be biased by certain factors; also that he can only see each crop once. Whoever the judge be, he will be limited by these same factors, and the only way of overcoming to a measure this disability, is by more entries, and so making the Competition stronger financially, so that expenses could be paid to two more judges and average of their estimates taken.

If actual yields could be taken as a basis of the Competition it would also overcome it, but there would be the danger of unfair methods being adopted, which would defeat the end of the Competition more quickly than anything else. Some farmers appear to lose sight of the fact that the crops are judged on ESTIMATED YIELD and that all crops are not in the same state of maturity when judged or seen in the same light or from the same aspect, and are disappointed because certain crops yield better than others that are estimated at a higher value. This is a difficulty that is hard to overcome, and it is more than probable that 20 judges would all get different results, and the only improvement that one can suggest is, as in the former case, three judges and take their averages.

The question of scale of points is another bone of contention, but any alteration would not produce any good results unless actual yield could be obtained. The committee no doubt are open to conviction on the matter and would be willing to back any system that could be shown to improve the efficiency and support of the Competition.

THE GAS PRODUCER ON A FARM TRACTOR.

[By L. Foale, Parilla.]

(*Pinnaroo Line Conference, Jabuk, August 4th.*)

In the course of this paper it is proposed to give as many points as will be necessary to give an outline of the gas producer as an economic proposition on a farm tractor, and to draw a comparison between a tractor which is guaranteed to do the work of 18 horses. The tractor has given great satisfaction on both petrol and kerosene, doing the work of 20 horses, pulling two 20-row combines during seeding and two spring-tooth cultivators of the same size working fallow. It did the work of 16 horses at fallowing time, working a 16-furrow gang plough; it has also worked two 14-discs sundercuts on rough ground. On good solid ground this tractor—which is a 30 Holt caterpillar—worked on top gear, with an occasional drop back to second on stiff grade, and to bottom going up sandhills. In heavy sandy country the tractor will only pull one machine; it has only drawn one 20-row combine on this class of country, but could easily work a 28-row machine.

With the gas groducer, the tractor loses from 15 per cent. to 20 per cent. of the power when working one machine only. It would work a 28-row combine or cultivator and a 16-furrow gang plough, but the pace is reduced from 30 per cent. to 35 per cent., which means that instead of doing from 5 to 6 acres per hour with petrol or kerosene, with the gas producer, taking into consideration that a stop to refuel must be made every 1 to 1½ hours, the acreage per hour is reduced to from 3¼ to 4 acres with the wider machines, and 2½ to 3 acres per hour with a 16-furrow gang plough. This gives some idea of the difference in the work which can be accomplished by the two fuels.

Costs.

One acre on petrol with petrol at 2s. 1⅞d. per gallon landed on the farm, including oil, costs approximately 1s. 5d. per acre; and on kerosene at 1s. 4d. per gallon, which had to be carted from station or depot, including oil, works out at approximately 1s. per acre.

A variation is also made if the working is light or heavy. My costs and working are based on a medium working of the land, on carbon monoxide gas produced from charcoal and water, with charcoal at a saleable value of £2 10s. per ton. The charcoal before being used must be rescreened and broken to a size a little larger than a walnut. This procedure entails a fair amount of work.

Fallowing with an 8-furrow heavy fallowing plough can be done for 5½d. per acre, cultivating fallow with a spring-tooth cultivator 3d. per acre, with a 16-furrow skim plough 4½d. per acre, seeding with a 20-row combine 3½d. per acre. These figures are approximate, but at the same time are very close to the mark. When the farmer makes his own charcoal, these costs are reduced very considerably, as the stumps *must* be carted off the land and can be carted straight to the pits for burning. The only outlay when the farmer makes his own charcoal is 1 to 1½ gallons of petrol per day, used for starting the tractor after each stop to refuel.

SORE SHOULDERS AND SORE BACKS ON HORSES.—PREVENTION AND CURE.

[By J. Bullen, Yurgo.]

There is an old saying, "Prevention is better than cure"; find the cause and the effects will disappear—such is the case in all animal ailments.

Causes.

Sores are frequently increased by ignorance, indifference, and want of intelligence. Bad-fitting collars and saddles are the most common cause. Conditions which influence the production of sores are the soft condition seen in horses that have done no work and are fat; poor condition of horses that are over-worked and underfed; dirty shoulders; rough work, such as rolling, logging, &c.; loose hames; undue pressure and friction. In fitting a collar or saddle it is important to study the horse's requirements.

Fitting the Collar.

First note the shape of the shoulders and the movements of the horse. The shoulders —when a horse is in motion—are constantly moving backwards and forwards, so that when fitting a collar bear in mind that while one shoulder is coming forward the other is going backwards, so that at no time does the collar rest on an even surface, as when the two shoulders are at rest.

Horses with upright shoulders, with well-developed muscles, are easy to fit and seldom give any trouble; while some are thick at the crest of the neck, others are thin, and some hollow in the neck. The collar should rest evenly on the shoulders and not be forced into position. It should fit closely to the neck without pinching, but should not rest on the neck in front of the withers. At this point there should be a space which will admit no more than the flat of the finger, and should be the same at the top and bottom of the collar, and no part of the fore wale or after wale should touch the horse. There should be no lateral movement. The best way to see if the collar is fitting properly is to take hold of the top of the collar with the right hand, and at the throat with the other hand, move the collar from side to side, at the same time pressing the collar to the shoulders. If there is play, the collar is too wide.

The next point is the depth of the collar. To test this, place the flat of the hand between the throat of the collar: if deep enough to take the flat of the hand it is all right—deeper than this is unnecessary and may be a source of trouble.

A new collar sometimes gives trouble, and it is well to soak the collar for about two hours in water before putting it on the horse, and it will go into shape more readily. Care must be taken to place a dry cloth or bag under the wet collar. Always keep the housing strap tight.

The hames should be fitted accurately into the space between the fore and after wale, care being taken that the draught is in the right place. On some makes of collars there is an extra piece of leather stitched on the after wale for the hame hooks to rest, and this also acts as a guide as to where the draught should be. The hame should be strapped firmly into position, in order to stop any up or down movement, but it must not pinch the collar.

Prevention.

Horses must be well groomed before any harness is put on them, and for this operation the oval scraper type of currycomb is favored, or a good dandybrush, paying particular attention to the shoulders and backs. As each horse is groomed, pass the hand down each side of the shoulders and on the back where the saddle fits, to see if there are any lumps or sores, &c. Always see that the collars fit properly. When horses are continually at work they begin to lose condition. This means a loose collar, which causes friction, undue pressure, and then sore shoulders. The remedy for this is to pack the collar until it is fitting again. To do this the use of clean super. bags is an excellent idea. First, cut off the double seam at the top of the bag, then fold the bag lengthways and place under the collar, care being taken that there are no creases in the bag. Look at both sides; it may be necessary to adjust the bag or bags before hooking on the chains. The broad hame hook gives a greater bearing surface and does not cut into the collar.

Another source of trouble is that some old collars become flattened and the after wale cuts into the horse. This trouble can easily be overcome by having the collar restuffed or by keeping the leather well greased and turning the leather outwards. For horses that are working on the pole of any implement, put a bag under the collar, because of the undue pressure on the top of the neck, owing to the lack of stuffing at this point of the collar. If the horses are troubled with boils on their shoulders a change of feed, such as wheat hay or a little sulphur in the feed and some laxatives—bran or Epsom salts in the feed—will effect a cure.

TREATMENTS THAT ARE WORSE THAN THE DISEASE.

Drivers occasionally place pads under their horses' collars to raise the collar off the sore. The remedy is worse than the sores, because the pressure on the shoulder is not even and very soon the horse has another sore where the pads have been. False collars—the type which are cut out of leather to fit the shoulder with one side smooth and the other rough—in theory these seem all right, but in practice they are, in my opinion, false. Oils and ointments only make the shoulders soft.

Remove the pressure and the sore will soon heal. To do this, cut the seam of a clean super. bag, fold it lengthways, then put a little smear of blacklead paste on the sore, place the bag in position where the collar fits, and place the flat of the hand over the sore; this will mark the bag with the blacklead. Then cut out a round hole three or four times larger than the mark. Place into position again and fasten the collar over the bag. If it still rubs, put another bag under, cutting it the same way as before. Always apply blacklead every time the collar is put on; this stops any of the bag or collar that may touch from sticking to the sore and making it worse.

Lumps may be treated in the same way, only in this case the black lead is not necessary; if the pressure is removed from a lump it will disappear, but this takes a long time.

The time to treat a sore is before it becomes too large, not when it is so inflamed and raw that the horse will not allow itself to be approached or touched. If the horse is unfortunate enough to be in this condition, which does sometimes happen in the case of a scald, then there is no alternative but to use a breastplate. These can easily be made out of a super bag, by first cuting off the double seam and folding lengthways; stitch a hook on about 6ins. from each end, but have no stitches next to the skin. Never make a breastplate too narrow—the broader the better. When working it has a sawing action, and this is obviously a greater source of friction. Always keep the breastplate clean; it has a tendency to soon become foul and caked with sweat.

SORE BACKS.

Sore backs are always brought about by a combination of friction and pressure. Always bear in mind that when a horse starts to lose condition it is from the muscles on the back that the flesh first disappears.

To fit a saddle the withers must not be pinched or pressed up. The central line of the back must have no pressure imposed upon it. The shoulderblades must have free movement. All the weight must be evenly distributed upon the muscles covering the top of the ribs attached to the spine, which extends from the play of the shoulderblades to the last rib. Always remember that a horse is not constructed to carry weight as are human beings. The muscles of the back act as a buffer, so that when a horse loses condition, bags will act as a good substitute. Sores on the back should be treated in exactly the same way as sore shoulders—by cutting a bag.

If a horse is being worked in a dray, always keep it well balanced; it is quite a common sight to see the driver riding right in the front of the dray and never shifting his position. It is just as bad with an empty dray or a loaded one. Bad sores should be bathed in a weak, warm solution of disinfectant, and if the horse is in a healthy condition the sore will soon heal. Boils should be lanced and the core taken out. "Do unto others as you would that they should do unto you." So apply the same to the horse, a good faithful servant.

THE ADVANTAGES TO BE DERIVED FROM A BUTTER AND BACON FACTORY AND FREEZING WORKS.

[By A. E. Howlett, Goode.]

(*Ceduna Conference.*)

Of late we have read quite a lot about prizes for export pigs, side lines competition, etc., in the *Chronicle*. The idea is indeed a good one and will prove beneficial to most farmers and the State in general. In the Ceduna district and the surrounding districts, however, I am afraid producers will derive no benefit whatsoever, because it is not possible to make the side lines a paying proposition by entering for competitions, even if there was a reasonable chance of taking a prize. We are too far away from the home market (Adelaide), railway freights and shipping rates, &c., being far too high for us to entertain the idea. For instance, a farmer in our locality forwarded to Adelaide five pigs, which realised £6 16s. 6d.. Charges for freight were £3 6s. 2d.; then he received word to say dock charges, &c., were yet to be deducted. The local market (Ceduna) is too small to be of any advantage whatsoever. The overseas market is right out of the question at present, because there are no facilities for disposing of products to meet the demand of an overseas market. After viewing the whole situation at a glance, it appears that there is no encouragement to go in for side lines on a firm basis.

After conversation with various settlers of long experience I am convinced that if we had an opening to compete in the overseas market the country is quite capable of carrying extra stock in all lines. If there was a butter factory at Thevenard—our deep sea port—we could then go in for cattle breeding and make it pay. The few cattle we have at present are indeed a very poor advertisement for the district, but as they keep the home going, that is all we need in our present position. There are a few farmers at the present time with about 15 to 20 head of cattle, but of a very poor type, and if they can keep them under existing circumstances, it is safe to assume that on an average a farm over here can carry 15 head of decent cattle.

Improve Your Herd with a Subsidised Jersey Bull.

THE "EUDUNDA JERSEY STUD"

CAN SUPPLY YOUR NEEDS WITH TYPE AND PRODUCTION-BRED BULLS.

We are offering

THREE CHOICE YOUNG BULLS

at the

ROYAL SHOW SUBSIDY SALE.

All of which are backed by Good Production Figures.

Further particulars apply—W. S. McAULIFFE, "Culgoa," Eudunda.

'Phone 11, Hampden.

It costs very little more to keep a good, sound cow than the weedy ones we now have. The first item would be to find out the right type of cow suitable to this district, then with the combined efforts of farmers to procure this type. We could only start in a small way, as also would the factory, so each farmer should purchase as many cows as he can reasonably afford, and one farmer, or group of farmers, get a good bull.

FODDER CONSERVATION.

Now comes the main question of feeding our stock; our carrying capacities will naturally be governed by fodder reserves, because we are subject to drought conditions. First of all we will take hay chaff mixed with oats. There are times when we get a reasonably good hay cut, so when the chance comes we should stack as much as possible. Our farms are gradually getting worn out, so far as wheatgrowing is concerned, "take-all" is becoming a menace, and as oats help to combat this I shall deal with it later on. Cocky chaff fed with oats is going to be a last resource in extremely bad conditions. The most important feed of all, in my opinion, is ensilage. This is the safest method of reserving fodder, because it is practically indestructible, neither fire, floods, rabbits, nor mice will damage it; if well made it will not rot or decay, and can be taken out after a short period, or years after, in the same condition as it was put there if the job is done correctly. The fundamental principles of ensilage are:—(1) Harvesting the crop in a perfectly succulent condition; (2) handling and storing it before the green stuff becomes withered or dried out; (3) storing or stacking in such a manner as to exclude air.

There are three methods most commonly in use—the pit silo, the overground silo, and the stack. Of the three, I recommend the pit silo. With a dam sinking plough, a 6ft. scoop, and four good horses, a pit to hold about 300 tons can be taken out in about a week. Ensilage can be made out of almost any natural plant growth, besides cultivated plants, but the safest plan would be to grow more oats. Supposing a farmer holds 2,000 acres. Divide this into five paddocks; No. 1 paddock 400 acres of fallow, No. 2 paddock would be wheat on previous year fallow, No. 3 oats on the wheat stubble, No. 4 and No. 5 would be left for grazing. Two hundred acres of the oats would be cut for ensilage, and by the time this was harvested the remainder would be ready for hay; 100 acres would then be cut for hay, and the rest could be reaped for feed and seed. The water question is most serious, because in parts we have no permanent water supply. Although a section of the country I have in mind is on the Tod River water scheme, settlers are unable to make full use of it now. Failing the extension of the Tod River water scheme, we should have to build more underground tanks. If at any time the water supply was low, it would be possible to take the products into the town and bring back water.

Dairying and pig breeding are interwoven, for after the cream has been disposed of there will be a surplus of milk, and the result of this means pig breeding. This is where the bacon factory and the local market come in, because the local market would work in conjunction with a bacon factory.

The prospect of freezing works in the district would involve the rearing of fat lambs. The Merino ewes would be kept for producing wool, and crossed with a mutton-producing ram, it would be possible to keep either a certain proportion of the flock for breeding further Merinos, or replenish the flock with new stock, according to the condition, age, etc., of the ewes required for breeding fat lambs.

With a combination of a butter and bacon factory and freezing works farming in these parts would be a better paying proposition, and more interesting, especially the livestock breeding activities. We should then have a certain amount of money coming in regularly; it would lessen the gap between good years and total failures. Our farms would have the change of cropping, which is an essential point; the townships of Ceduna and Thevenard would benefit, because their unemployed would have constant work; farmers with families would have a means of providing work of interest for their boys and girls; we would have the opportunity of boosting and advertising our district; vacant blocks would no doubt be taken up; we would be able to run an agricultural show and take pride in it; and the railways would increase their revenue.

DISCUSSION.

Prof. Perkins stated that he agreed that it was very difficult for farmers in the distrist to engage in side lines to the same extent as those nearer the markets. Nevertheless, it should be possible in course of time to attain markets which would bring in a profit for their side lines. He had the advantage of keeping the accounts of a private farm in the Murray mallee. The farmer had had two wonderful seasons and had been able to grow wheat at 3s. 5d. a bushel after providing for a salary allowance. That was only possible because the farmer did something more than grow wheat. If he had grown wheat only, the wheat crop would have carried the whole of the cost of working the land, interest on capital and land valuation, rates, taxes, depreciation, and so on. The figures represented approximately £1,200, allowing for a salary of £300 for the farmer. This man kept a flock of sheep. The mere fact that he had these sheep relieved the wheat crop of portion of the £1,200. If he had no sheep and grew wheat over the whole of the farm once in three years the cost would have been 4s. 2d. per bushel, and over a four-years' rotation it would have cost 5s. 2d. Side lines, therefore, relieved the wheat crop of part of the costs, as all charges of the grazing area went to the sheep account.

Mr. W. L. Edson (Laura Bay) stated that he had a small farm and he would not give consideration to the keeping of cows as a side line. A butter factory was out of the question, as it would be too costly to run. Last year's crop paid him well, and if a farm could not be made to pay by sheep and wheat it could not be turned to profit by cows.

Mr. Howlett said if it could be proved that ensilage could be made in the district more people would go in for cows. He considered that there was a reasonable chance of making good ensilage this year. Some farmers were not making the full use of the Tod River where available. Even if everyone kept five cows the scope of producing butter was big enough to keep a butter factory going.

Mr. B. O. Klau (Goode) stated that it was a question of seasons. Last season quoted by Mr. Edson was an exceptional year. The matter should be placed on an average basis, say, over 20 pears, and he was of opinion that a farmer keeping side lines would be better off at the end of that period than one who ignored them. Side lines had pulled farmers through in other parts, and they would do the same in the Ceduna district. So long as farmers had good seasons everything went along all right without side lines, but two or three bad seasons would absorb all they made in good seasons.

TO-DAY

TO-DAY IS THE TO-MORROW YOU WERE THINKING OF YESTERDAY.

There is hardly anything that the average person procrastinates about quite so much as money saving, despite that the same average person has a comparatively small income, knows that he must spend carefully and save wisely, and knows, too, the best way to do it.

HAVE YOU DONE TO-DAY WHAT YOU YESTERDAY PUT OFF UNTIL TO-MORROW?

You can open a Savings Bank Account anywhere, because the Commonwealth Savings Bank is represented in every district in Australia, and with any amount, from One Shilling upwards. It is so easy—you have only to register your signature and deposit your shilling (or more) and you will have started on your saving campaign to-day.

Commonwealth Savings Bank of Australia

(E. C. RIDDLE, Governor).

Mr. Barlow (Chief Dairy Instructor) stated that the biggest question was that of marketing. He pointed out, too, that whatever side lines they took up must be managed intelligently, as it would be of no use keeping a few cows, pigs, and poultry and letting them run about the farm looking after themselves. The question of type in their stock was also of importance, just as good seed was necessary for growing of wheat crops. Although farmers were inclined to look down on cocky chaff as a drought food, he knew where this chaff—used properly—was giving good returns. By mixing with oats (crushed or whole) and feeding it with good oaten chaff wonderful returns were being obtained from 15 to 20 cows. It was being properly conserved, and in one instance a farmer had built a shed purposely to store the cocky chaff. With green feed that might be available and crushed oats it would give good results.

The making of ensilage should also be taken seriously. In a district like Ceduna they must have something to compare with natural pasture during dry periods. Even in the worst seasons there was generally something that could be turned into ensilage. The ideal was to harvest the crop in a succulent condition. If on the ripe side comparatively good results could be obtained by the addition of water when the ensilage was being made. Cereals, barley grass, and wild oats should be cut just as the heads were beginning to show. Whatever crop was being used it should be put into the stack before it began to wilt, and cut only what could be stacked the same day. The whole secret of making good ensilage was to exclude the air, and the quicker this was done the better the results. The only way to exclude the air from the stack or pit was by putting on as much weight as possible. There was no limit to the weight, and once the air was excluded and the material well compressed it would last a long period; he had seen it last eight years in very effective condition. The best improved country, continued Mr. Barlow, was that where the land was carrying livestock. Growing wheat alone appeared to him as a purely mechanised job, but an additional interest was given to the work of the farmer if he bred his own livestock. The men who were doing best out of land were those who were making money out of the natural increase of livestock on their holdings. In the pig trade the type and size of pigs controlled the price, and pigs should, therefore, be of proper size and well looked after. The only way to make a profit out of them at present was to put them on the market in the quickest possible time—not much more than, say, five months old. If they are kept, say, seven months, there would be a loss. Farmers should give a lot of consideration to the question of establishing a butter factory at Ceduna before taking any definite steps, as there would be a loss over the first few years.

He referred to the arrangements made with the freezing works at Port Lincoln to receive pigs when the works began treating lambs. Private negotiations are also being made to open the works as a bacon factory. He advised the farmers to co-operate in the matter of trucking instead of sending pigs in separate consignments. The Railways Department was willing to do anything reasonable with concerted action, but it could not be expected to cut freights for a few pigs sent by a single individual. Under the present conditions of the market it might be necessary to alter the type, as a lot of pigs were unsuitable. The bacon type would be the best kind to sell.

Mr. Shepherd told the delegates that many people in the South-East sent, say, half a truck of pigs at a time, and he thought that the railways would meet farmers on Eyre Peninsula similarly to those in the South-East. A cattle truck would hold about 60 pigs.

In reply to questions Mr. Barlow said buyers would take butter if it were bulked, but the difficulty would be to devise some means of bulking it. It would be necessary to send it at least once a week, but as in the case of marketing pigs the farmers must co-operate.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE AT EYRE PENINSULA (WESTERN).

The Conference of Branches of the Agricultural Bureau situated on the western districts of Eyre Peninsula was held at Ceduna on Wednesday, July 6th. Mr. N. D. McConechy (Maltee) presided over an attendance of delegates from Maltee, Goode, Laura Bay, Smoky Bay, and O'Loughlin. Others present were Messrs. S. Shepherd (Advisory Board of Agriculture), Professor Perkins (Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), W. H. Brownrigg (Agricultural Instructor), H. C. Pritchard (General Secretary Agricultural Bureau), and A. H. Robin (Veterinary Officer of the Stock and Brands Department. The local arrangements were ably carried out by Mr. E. Schwarz (Maltee).

The Conference was opened by Mr. S. Shepherd, who stated that in order to make a financial recovery South Australia must, in common with other States and other countries, get down to bedrock, but when the farmer was handicapped by tariffs there was very little encouragement for him to persevere. As an example, to-day it took 216 bushels of wheat to buy a ton of galvanised iron, whereas a few years ago the equivalent was only 95½ bushels. Many farmers, however, were given to extravagance and had sacrificed their teams for the purchase of tractors. If they had listened to the advice of Professor Perkins years ago they would be better off to-day. Farmers now realised that it was a good investment to breed horses, particularly if they had mares capable of throwing good stock. Renewed consideration should also be given to sheep, as wool would again be a profitable source of revenue. The hardy robust types of Merinos would live longer without water, would travel better than other breeds, and would eventually be a valuable adjunct to a mallee farm.

He considered that the Agricultural Bureau was of the greatest value to producers. There were over 8,000 members, and there was no reason why there should not be more. He pointed out that a member of the Bureau was virtually a member of the Department of Agriculture. Some farmers had said that the Bureau was of no use to them, as other members could not teach them anything. Even if that were true, it was a selfish view as it was the duty of such farmers to come forward and help others.

Mr. Shepherd said by meeting men in country districts he was, personally, still learning. The Bureau was the best means of getting in touch with farmers in his own as well as in other centres of the State. He paid a tribute to the work of the Agricultural Instructors, and he advised members to consult those officers when in difficulties over their farming problems.

He said he was pleased to see that the district was having a wonderful season, but he reminded his audience that they should not forget that they had experienced worries in the past and they must therefore not forget to make provision for the future. He knew of one district where, in the 'nineties, farmers tore down their sheds to feed their stock, whereas if they had conserved their fodder they would not have experienced any food shortage. Any fodder was better than no fodder, so long as it was well looked after and properly stored. He had a straw stack 16 years old on his farm, and it was still in good order. Although he got a consistent rainfall at Kybybolite, he conserved some fodder each year for safety.

He could see no reason why they in the Ceduna district could not grow wheat cheaper than in any other part of the State. The cost of production would, however, have to come down. Farmers could not go on paying £20 for wire when its economic value was only £10. If the farmer was robbed of his tools of trade an uneconomic condition arose. He reminded them that, on the other hand, if they must import goods they should buy those which were economical and would last for years.

In conclusion, Mr. Shepherd referred to the Turretfield farm, which was now being used as a seed wheat farm. He appealed to farmers to patronise it as much as possible. He said he hoped that they would eventually get Minnipa back as an experimental farm, as this class of departmental activity was of utmost assistance to wheat farmers.

Papers were read by Mr. L. B. Hughes (Goode), on ''Experiences During Two Mouse Plagues''; Mr. A. E. Howlett (Goode), ''Advantages to be Derived from a Butter and Bacon Factory and a Freezing Works''; and Mr. B. A. Klau (Goode), ''The State Bank and the Farmer.''

Several questions were answered by Departmental Officers, and at the conclusion of the Conference, Mr. A. H. Robin gave an address on ''Stock Diseases.''

The following resolution was carried: ''That delegates to Congress attend two-thirds of the session, and that the General Secretary be asked to notify Branches the number of sessions attended by their respective delegates.''

It was decided to hold the next Conference at Ceduna under the auspices of the Smoky Bay Branch.

CONFERENCE AT BLACK ROCK.

Upper Northern Branches of the Agricultural Bureau met in Conference at Black Rock on Wednesday, July 20th. There was an excellent representation of delegates from the Wepowie, Orroroo, Morchard, Eurelia (men's and women's), Willowie, Murraytown, Black Rock, Jamestown, Tarcowie, Wilmington, and Wirrabara Branches.

Messrs. F. Coleman (member of the Advisory Board of Agriculture), Prof. A. J. Perkins (Director of Agriculture), C. F. Anderson (Poultry Expert), W. G. Bennett, B.V.Sc. (Veterinary Lecturer, Roseworthy Agricultural College), E. L. Orchard and J. O. Hatter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary, Agricultural Bureau) attended on behalf of the Department of Agriculture.

Mr. C. T. Kuerschner presided, and the secretarial duties were in the hands of Mr. R. E. Kitto. Mr. F. Coleman delivered the opening address, and the following papers were read and discussed:—''The Value of Sheep on a Farm in the Upper Northern Areas,'' Mr. E. H. Hampel (Wilmington); ''Pig Breeding and Bacon Curing,'' Mr. J. G. Schuppan (Wilmington); ''Producer Gas Power for the Farmer,'' Mr. L. Judell (Jamestown).

A large number of questions were answered during the Free Parliament session, and the following resolutions were carried:—''That the 1933 Conference be held at Morchard.'' ''That the second terminal school holidays be held concurrently with the Adelaide Royal Show.'' ''With the view to encouraging more country subscribers, the Postmaster-General be requested to make a 25 per cent. reduction on rentals for all subscribers over three miles from an exchange who have been connected for a period of seven years or more.'' ''That as soon as possible after seeding each year the names of the wheats that are available at the Turretfield Farm, and also the approximate costs or terms under which same may be procured, be published in the *Journal of Agriculture.*'' ''That the Government be asked to send out veterinary surgeons into the country to investigate when two or more stock die from an unknown cause.'' ''That the compulsory rule *re* new members taking the *Journal of Agriculture* be rescinded.'' ''That this Conference requests the Department of Agriculture to investigate the adaptation of the use of producer gas fuel for general use in tractors in South Australia.'' Conference concluded with an address, ''Prospects of the Coming Export Season for Eggs,'' delivered by r. C. F. Anderson (Government Poultry Expert).

KAROONDA CONFERENCE.

Branches of the Agricultural Bureau constituting the Western Division of the Murray Lands area met in Conference at Karoonda on Tuesday, August 2nd, 1932. Mr. C. S. Coombs (Kulkawirra) presided and the secretarial duties were carried out by Mr. H. J. Elliott, delegates being present from the following Branches:—Wynarka, Karoonda, Borrika, Kulkawirra, Copeville, Windsor, Nunkeri, Kalyan, Yurgo, Marama, and Bowhill.

The Department of Agriculture was represented by Messrs. J. B. Murdoch (Member Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert), W. G. Bennett, B.V.Sc. (Veterinary Lecturer Roseworthy Agricultural College), R. L. Griffiths, P. H. Suter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

The opening address was delivered by Mr. J. B. Murdoch, and, at the instance of Mr. H. Brown (Borrika), seconded by Mr. G. Tregilgas (Yurgo), it was decided to place on record a vote of appreciation to Mr. Murdoch for his interesting address.

The following papers were read and discussed:—''Sheep for the Farming Districts of South Australia,'' Mr. R. Elliot (Kulkawirra); ''Wheat Diseases,'' Mr. A. P. Hein (Kulkawirra); ''Sore Shoulders and Sore Backs on Horses,'' Mr. J. Bullen (Yurgo); ''The Problem of Making Farming Pay in the Mallee,'' Mr. H. Sanders (Yurgo); ''Grasses for the Mallee,'' Mr. C. L. Bruce (Karoonda).

A certificate conferring the honor of Life Membership of the Agricultural Bureau was presented to Mr. A. Hood by Mr. Spafford. Addresses were delivered by Messrs. C. F. Anderson, H. B. Barlow, and W. G. Bennett. Numerous questions were answered by Officers of the Department, and the following resolutions were adopted:—

''That the 1933 Conference be held at Karoonda with arrangements in the hands of the Wynarka Branch.''

''That in view of the increasing importance of the keeping of livestock, it is recommended that allowances for fencing be made immediately available and more liberal and that the Act be administered by the Government on the advice of the district councils.''

''That this Conference requests the Government to transfer one of the Veterinary Officers of Stock and Brands Department to the staff of the Department of Agriculture for the purpose of giving advice to farmers.''

Conference concluded with an address, ''Stock Ailments,'' by Mr. W. G. Bennett, B.V.Sc.

PINNAROO LINE CONFERENCE.

The Annual Conference of Pinnaroo Line Branches, attended by an excellent representation of delegates from the Lameroo, Geranium, Parilla, Clanfield, Lameroo, Pinnaroo, and Parrakie Branches, was held at Jabuk on August 4th. The chair was occupied by Mr. F. Elwood (President of the Geranium Branch of the Agricultural Bureau). Mr. L. S. Prouse acted as Conference Secretary. Messrs. A. L. McEwin (Member Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agri-

culture), H. B. Barlow (Chief Dairy Instructor), W. G. Bennett, B.V.Sc. (Veterinary Lecturer, Roseworthy Agricultural College), C. F. Anderson (Government Poultry Expert), P. H. Suter, R. L. Griffiths (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary, Agricultural Bureau) attended on behalf of the Department of Agriculture. The agenda was a lengthy one, and included the following papers:—"Crop Competitions," Mr. R. C. Jacobs (Geranium); "Sheep and Wool on the Farm," Mr. T. M. Rice (Pinnaroo); "Producer Gas for Tractors," Mr. J. Foale (Parilla); "Horse Breeding," Mr. D. McKenzie (Pinnaroo); "The Origin and Objectives of the Lameroo Horse Breeding Society," Mr. W. F. Morcomb (Lameroo); and an address, "Sheep in Mallee Areas," by Mr. W. J. Spafford (Deputy Director of Agriculture).

Mr. A. L. McEwin presented to Mr. D. Orwell, of the Clanfield Branch, a Life Membership Certificate of the Agricultural Bureau.

RESOLUTIONS.

During the session devoted to Free Parliament, a large number of questions were discussed, and the following resolutions were carried:—"That the 1933 Conference be held at Pinnaroo with arrangements in the charge of the Parilla Well Branch; failing this, Parilla Branch will hold the Conference at Parilla"; "That this Conference ask the Government to renew the subsidy previously granted to Crop Competitions because of their influence on wheat-growing and the dependence of the recovery of the State on this industry"; "That in the opinion of the Conference existing legislation should be altered to permit of clean used super. bags being used as containers for livestock foodstuffs"; "That this Conference strongly protests against the high price of superphosphates"; "That the Government considers the advisability of introducing a scheme whereby groups of farmers will be enabled to purchase high-class stallions"; "That in the opinion of this Conference, Congress should be directed that the new rule *re* membership should be rescinded, and that a *Journal* levy on all members be introduced and paid by each Bureau member entitling him to a copy of the *Journal*"; "That this Conference desires an extension of time for the concession rates on super. carried on the railways to April 30th each year"; "That this Conference urges the Government to increase the travelling allowances of the Agricultural Instructors to allow them to get out amongst the farmers more than at present"; "That the postal authorities be urged to allow at least Adelaide bound letters from Wilkawatt, Parrakie, Geranium, and Jabuk to be carried on the lines on Saturday mornings. This would not entail longer hours to the post officers concerned, but would be a boon to the districts concerned"; "That the Department be requested to supply copies of the judges' full report of Crop Competitions to members of the Committee and Secretaries of Branches within the district"; "That in the opinion of this Conference and in view of the importance of the wheat-growing industry to the State, the subsidy to wheat-growing Competitions should be renewed"; "That Conference urges that the Department of Agriculture endeavor to arrange a date during the last week in September to hold the next Pinnaroo Line Conference"; "That Conference strongly urges that the Minister of Railways provide (without the usual guarantee) a rail car for delegates to travel on our railway to District Conferences."

Mr. H. G. Johnston (Secretary of the Chandos Crop Competition) read the annual report and balance-sheet, and trophies as follows were handed to the successful competitors by Mr. McEwin:—First prize, Mr. P. Ross, Parrakie, 93½ points (gold watch); second prize, Mr. W. N. Johnson, Parilla, 89 points (grandfather clock); third prize, Mr. H. G. Angel, Pinnaroo, 88½ points (rose bowl); fourth prire, Mr. W. J. Ross, Parrakie, 88 points (inkwell). *Junior Competition.*—First prize, C. G. Johnson, Parilla, 87 points (silver cup); second prize, M. Hutchens, Parilla, 86½ points.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, July 27th, there being present:—Messrs. H. N. Wicks (Chairman), A. J. Cooke (Vice-Chairman), F. Coleman, A. M. Dawkins, S. Shepherd, A. L. McEwin, P. J. Baily, J. B. Murdoch, Professor A. J. Perkins (Director of Agriculture), and H. C. Pritchard (Secretary). Apologies were received from Messrs. P. H. Jones and J. W. Sandford.

Re-appointment of Members.—Messrs. P. J. Baily, F. Coleman, A. J. Cooke, A. M. Dawkins, P. H. Jones, and H. N. Wicks, who retired by effluxion of time on June 30th, 1932, were re-appointed by the Hon. Minister of Agriculture for a further period of two years.

Appointment of Chairman and Vice-Chairman.—Mr. H. N. Wicks was appointed Chairman and Mr. A. J. Cooke Vice-Chairman for the ensuing 12 months.

Size and Quality of Cornsacks.—Information was received from the Comptroller-General of Customs that the necessity for close supervision in order to ensure that the prescribed conditions are maintained has been strongly brought under the notice of the Collector of Customs in the several States. The Secretary was instructed to report this matter to the Annual Congress.

Telephone Rentals and Subscribers' Book.—The following resolutions were carried at the Upper North Conference:—"With a view of encouraging more country telephone subscribers the Postmaster-General be requested to make a reduction on rentals for all subscribers"; "that the Postmaster-General be approached and requested to publish a telephone subscribers' book including all telephone subscribers in the State of South Australia." It was decided to bring these requests under the notice of the Postmaster-General's Department.

Southern Conference.—The Board agreed to the request of the 1931 Southern Conference for a division of this district, and decided that the place of holding the Conference of the Western Division should be placed on the agenda of the 1932 Southern Conference.

Life Membership.—The names of Messrs. G. G. Pitt (Balhannah), A. Hood (Wynarka), and D. Orwell (Clanfield) were added to the roll of Life members of the Agricultural Bureau.

New Branches.—Application was made by the Metropolitan Dairymen's Association to establish a Branch of the Agricultural Bureau. The Board conditionally approved of the formation of the Branch, to be known as the Adelaide Branch of the Bureau. Approval was also given to form a Women's Branch at Balumbah, with the following ladies as foundation members:—Mesdames Rowe, Swann, H. Wohling, Ellis, Norris, Jericho, Deer, S. Wohling, Franklin, Riches, L. Stutley, and Marinho.

Alteration of Locality of Branch.—The Board decided to close the Clare Branch and to grant a transfer to Stanley Flat.

Change of Name of Branch.—Approval was given to change the name of the Bunora Branch to Balumbah.

New Members.—The following names were added to the rolls of existing Branches:—Streaky Bay—J. H. Heron, L. Lindquist, D. M. Drever, J. N. Drever, J. C. Drever; Pinnaroo—T. M. Rice; Mangalo—D. Munday, C. Brus, L. Brus, H. Mackley, M. Hannemann, O. E. Hannemann, C. Hannemann, S. Hannemann, R. Hannemann; Snowtown—G. Woodhouse; South Kilkerran—O. W. Arnold, L. E. Hasting; Redhill—T. H. Torr, jun.; Streaky Bay—J. L. Carter; Saddleworth—A. J. Jones; Parilla Well Women's—Mrs. C. Holmes; Modbury—E. Strahan; Paskeville—S. H. Sloan; Mount Compass—A. C. Gibson; Penola Women's—Mrs. W. Mitchell, Mrs. F. O. Lynn, Mrs. A. H. Reschke, Miss K. Sharam, Mrs. E. Kidman, Mrs. S. Waters, Mrs. C. F. Provis; **Penola**—J. G. Harmer, E. Kidman, C. McMurtrie, R. H. Milway, C. F. Provis; **Langhorne's Creek**—B. Norman, H. G. Norman; **Cungena**—R. Adkins, C. F. Nykiel, L. Hollamby, S. H. Bennie; Gladstone Women's—Miss Stephenson, Mrs. E. S. Hillard; Belalie Women's—Miss Mitchell, Mrs. C. Crouch; Kelly—H. E. Pearson, T. Hutchens, R. J. Beinke, F. R. Illman, I. W. Bartram; Balhannah—M. T. Cameron, Dr. Linn, B. Hector, L. Johncock; Berri—W. H. Chilton, G. D. Colton, M. Lean, E. Rout; Ashbourne—H. Sullivan, E. W. Jarman; Brownlow—E. Boehm, R. Steinborner; Belvidere—C. Cross, J. Vivian, sen., A. B. Eckert, B. Westley.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. Sandford & Co., Limited, reported on August 1st, 1932:—

Butter.—Splendid weather conditions continued throughout July, and with precipitations of rain every week, interspersed with moderate temperatures, has resulted in the pastures coming forward apace. Production of dairy produce has therefore steadily increased, and the outlook for the season is very promising indeed. Already heavy quantities of butter are going forward each week to London, and owing to the standard of quality being satisfactory, there has been no difficulty in disposing of the surplus. Choicest creamery fresh butter, in bulk, 1s. 2¾d.; prints and delivery, extra (these prices are subject to the stabilisation levies); well conditioned store and collectors', 8½d. to 9½d. per lb. at store door, less usual selling charges.

Eggs.—These also have shown a seasonal increase, but until sunnier conditions obtain, the improvement is somewhat slow. In the meantime, however, shipments are being packed for London, and owing to the local prices this season being considerably in advance of last year's values, producers are materially benefiting from this profitable side line on the farm. Ordinary country eggs, hen or duck, 10½d. per dozen; selected, tested, and infertile, higher.

Cheese.—The South-Eastern factories are marketing increased quantities each week, and report that the conditions in that part of the State are most favorable. Several shipments have already been made this season to London, and it is expected that record quantities will go forward during the balance of the season. New makes, large to loaf, 7¾d. to 8¼d.; semi-matured and matured, 10d. to 11d. per lb.

Bacon.—The consumption of bacon during the winter months is always much greater than during the warmer period of the year, and althought the turnover throughout July was well maintained, the factories were able to meet all requirements of the trade without difficulty. Values have continued fairly steady, and with supplies of live hogs in the Abattoirs and other markets being plentiful, no difficulty is anticipated with regard to stocks during the coming months. Best local sides, 8½d.. to 9d.; best local factory cured middles, 9¼d. to 9¾d.; large, 8½d.; local rolls, 6½d. to 7d.; local hams (raw), 1s. to 1s. 0½d.; cooked, 1s. 2d. to 1s. 3d.; lard, prints, 6d. per lb.

Almonds.—The supplies of almonds were fairly large during the month under review, but throughout buyers operated freely, and all lots met with ready clearance. Values have continued fairly steady. Brandis and softshells, 9d. to 9½d.; hardshells, 5d. to 5½d.; kernels, 1s. 11½d. to 2s. per lb.

Honey.—Ample stocks of all grades were available throughout July, and although local trade was well maintained, there was only a limited interstate trade available, and considerable stocks were carried over at the end of the month. Prices are steady. Prime clear extracted, in liquid condition, 4d. to 4½d.; second grade, 2d. to 3d. per lb.

Beeswax.—Meeting with good demand; 1s. to 1s. 1d. per lb.

Live Poultry.—Our markets were fairly well supplied throughout July, with consignments both from country districts and suburban yards, and keen competition resulted. We anticipate that the strong winter demand will continue as none of the poulterers at present are carrying extensive stocks. We advise consigning. Crates loaned on application. Prime roosters, 3s. 6d. to 4s. 6d.; well conditioned cockerels, 2s. 9d. to 3s. 4d.; fair conditioned cockerels, 2s. 3d. to 2s. 8d.; chickens, lower; heavy weight hens, 2s. 8d. to 3s. 7d.; medium hens, 2s. 2d. to 2s. 7d.; light hens, 1s. 8d. to 2s. 1d.; couple of pens of weedy sorts, lower; geese, 3s. 6d. to 4s. 6d.; prime young Muscovy drakes, 3s. 9d. to 5s. 3d.; Muscovy ducks, 2s. 3d. to 3s.; ordinary ducks, 1s. 9d. to 2s. 1d.; ducklings, lower; turkeys, good to prime condition, 8d. to 9½d. per lb. live weight; turkeys, fair condition, 6d. to 7½d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 4d. to 5d. each.

Potatoes.—6s. per cwt.

Onions.—New season's, 23s. per cwt.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

REPORTS OF BUREAU MEETINGS.

WOMEN'S BRANCHES.

INQUIRY DEPARTMENT.

[*Replies supplied by* MISS E. CAMPBELL, *Dip. Dom. Econ., Education Department.*]

Penola—"What is the best method to soften hard water for household purposes?"

By means of a mechanical water softener a continuous supply can be obtained. These appliances cost from £15 to £40 according to the capacity and to the state of hardness of the water. The method that was used in years gone by was to expose the water in open tanks and allow the air to cause the minerals to settle at the bottom of the tank, or a tub could be used. This method is the best, but it takes time, and there is the difficulty of drawing off the water without disturbing the sediment. For smaller quantities of water, boiling will cause the minerals to be precipitated. They will then form a crustation on the kettle or saucepan. For laundry purposes, there are various chemicals that can be added, such as borax, soda, ammonia, an excess of soap, but care should be exercised, as the soda, ammonia, and excess of soap will destroy the color of materials.

Belalie—"What is a coddled egg?"

A coddled egg is a very lightly cooked egg. Have the water boiling in the saucepan, place the egg in the water, put the lid tightly on the saucepan, and remove it from the stove. Allow the egg to remain in the saucepan whilst the water is cooling, and then the egg will be very lightly set. An average egg takes about five to seven minutes.

Belalie—"How to make oatmeal jelly?"

A clear jelly cannot be made from oatmeal on account of the starch it contains. The following is a recipe which makes a very tasty mould:—

Ingredients.—One tablespoon oatmeal, ½ pint cold water, pinch salt, ½ teaspoon sugar.

Method.—Soak the oatmeal in the cold water for half an hour; then stir well and strain through a fine strainer to remove all the husks. The husks are discarded. Add the salt and sugar to the liquid and bring it to the boil, stirring well. Simmer for eight to 10 minutes, stirring occasionally. Pour into wetted mould and allow to set, when it will turn out easily. A little nutmeg or cinnamon may be added to the liquid before it is brought to the boil, but this will flavor and color the mixture, and the mould will not be quite so clear.

Kangarilla—"What makes split peas remain hard in soup?"

Peas contain a lot of starch, and when they are dried, as for split peas, the starch cells become very hard. If the split peas are well covered with cold water and allowed to soak over night, they will become quite soft, and the water in which they have been soaking should be used in the soup.

Kangarilla—"Would it harm a child to eat raw vegetables, including potatoes, cauliflower, marrow? Child will eat any sort of vegetables raw, but will not eat them cooked.

No; it does no harm to eat raw vegetables, but they should be thoroughly washed and well masticated. If swallowed in large pieces they may cause digestive troubles. It seems as though the child's system is requiring the mineral salts. Try not to overcook the vegetables, thus preserving their full value, and always drain them well before serving.

Kalangadoo.—*What is the cause of hard butter, and a remedy to correct this fault?* The Chief Dairy Instructor (Mr. H. B. Barlow) says:—"Hard butter may be due to several causes, of which cold weather and the type of food available are the chief. Cows in an advanced stage of lactation are also more likely to give a firmer butter. With farm butter, the usual cause of the butter being hard and brittle in cold weather is that it is not worked sufficiently. Owing to the fact that factories are able to control the churning temperatures they work the butter for from 35 to 45 hours, and thus obtain what may be termed a 'spreadable' butter. Work the butter as much as possible after churning, allow it to set over-night, and then re-work until soft and almost greasy. This will have a decidedly beneficial effect. If only one or two cows are kept the addition of about 1lb. of linseed meal to the feed will probably assist in giving a softer fat, and will at least be beneficial to the cows."

BELALIE (Average annual rainfall, 17.75in.).

June 14th.

The meeting held on June 14th took the form of an exhibition of ancient and modern work. It was well patronised by visitors and members. There was a wonderful display of ancient articles. Three samplers were worked in 1701, 1790, and 1818 respectively, whilst a snuffbox which had once been in the possession of Sir Francis Drake and a tiny piece of brocade from a lady's dress took one back to the reign of Queen Elizabeth. Silver spoons over 200 years old, original willow and mason pattern plates, sixteenth century candlesticks, a small teacup as used in 1700, a seventeenth century goblet, a carpenter's morticing gauge 200 years old, ancient jewellery and books, were particularly interesting. Articles from Japan, China, India, New Zealand, and Siam gave an idea of the arts practised in other lands. Some wonderful hand-woven linen was also displayed; one linen sheet had been woven in County Clare, Ireland, 150 years ago, and a pair of blankets which had been hand woven in Scotland 100 years ago and used constantly. An interesting exhibit was a picture made of wool flowers, which had been made by two sisters in Jamestown over 40 years ago. Competitions were also held for the best and most interesting articles made in the home, not to exceed more than four articles. There were 12 entries and a great variety of useful and interesting articles. The most beautiful was a large rug made from blue and grey flannel, which was a work of art. Other collections contained knitted articles, fancy needlework, dressmaking, mats made from cast-off clothing, preserves, home-made toys, sweets, bread, soap, leather work, chip carving, and painting. The winning exhibit consisted of a beautiful hand-knitted cardigan, tapestry firescreen, stained book ends in wood, and a leather book cover. The second prize exhibited a lovely carved table, painted picture, crochet trimmed nightdress, and home-cured ham. The exhibition was in every way a success, and was appreciated by all who attended. (Secretary, Mrs. F. Cummings, Jamestown.)

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

CLARE (Average annual rainfall, 24.54in.).

June 4th.—Present: 12 members and four visitors.

Dress Cutting and Fitting.—The following paper was read by Mrs. A. Rogers:—"The first thing to do when cutting out a dress is to determine the right side of the material. If there is a pronounced diagonal weave, as in serge, hold the material against you and use the side with the twill passing from left to right. When the warp and woof are square in appearance, as in hopsack, linen, and plain silk, hold up to the light and use the smoothly finished side. When looking down on velvet the dark side must face upward. Measure the figure accurately and just large enough, and when cutting allow an inch or two where plenty of freedom is required. Then allow for all turnings. It is necessary to make a pattern or else procure one. A good plan is to save a plainly fitted dress, and when worn out cut a pattern from it and almost any style can be worked up. Keep to the straight of the material as far as possible. It is easier to cut from plain and small designs than stripes. Careful and thoughtful cutting is time saved at the end of the work. A design for a plain home frock is one with the top cut to the hip line, with a double inverted pleat at either side of the skirt and a belt at the waist, with full length, plain sleeve. The surest way of cutting is to place all pieces of the pattern on the double of the material. Cut all the large pieces of the pattern, taking thought for collars, cuffs, facings, and other small parts, but cut these after a preliminary fitting. Before pinning the pattern together, mark the centre line with contrast cotton without making a knot. The only time a knot is needed is in a thread for gathers. Proceed with fitting by placing the back and front on the figure with the centre line well placed. Fit the shoulder seam, taking out all the pins if not quite satisfactory. Then smooth upwards, having the front taut and the back eased in a trifle. This seam should be well over the shoulder line, and will help to make the back appear straight. The under-arm seam often needs the front piece either raising or lowering according to the demands of the figure, while a dart at the bust line would be an improvement. Care must be exercised with the armhole. Have it comfortably fitted but not too large. The sleeve needs to be rather larger than the armhole, and if eased in will set satisfactorily. If the shoulder seams are well fitted the collar should present no difficulty. Pin the centre of collar to the centre of the back, and if "worked in" a trifle in the middle of the back will be quite comfortable. The skirt must have the side seams shaped and the pleats placed parallel. Put the pleats in before fitting the seams, being careful that the size at the top of the skirt exactly corresponds to the hip-fitting of the dress. Having fitted one side, take all pieces apart. Rectify the fitting by placing the corrected half on the other and cutting the two alike. The length of the dress is the last thing to arrange, although the full length measurement is decided at the beginning, but by leaving the hem until last a little more or less can be put in it." (Secretary, Mrs. Rogers.)

McLAREN FLAT.

June 2nd.—Present: 17 members.

Duck Raising.—Mrs. J. Bruce contributed the following paper:—"The provision for duck breeding need not be so elaborate as in the case with fowls. It is always necessary to have shade for ducks and ducklings. A place made of wire netting, not too high and covered with straw, will make a good shade in their yards, and ducks as a rule disdain a house, but like a sheltered spot in which to camp. Any cool, but dry, spot will serve as a breeding, laying, or rearing house, but the nest must be dry. It is advisable to see that the nests are a little above the ground level. Heavy breeds require a pond, say, 12in. deep. It should be in a separate enclosure to be under control. Young ducklings do not require water to swim in; they must be kept as dry as possible, snug, but not overcrowded, and provided with fresh air. One main essential to success is to keep plenty of fresh water in the water vessels day and night. These should be in one corner of the yard and always kept filled. Ducks must always be watered before they are fed, and watered at least three times a day. The water vessels must be deep enough to allow the birds to dip their heads, otherwise bad eyes often develop. The plan is sometimes adopted of putting a brick in the vessels or cyclone wire over them so that the ducklings cannot get drowned. Young ducklings need not be left with their mothers many weeks. They can be put into a house by themselves, but they must be sheltered from the cold or heat and have dry sleeping quarters, with plenty of dry straw. If one is handling, say, 50 birds, it is advisable to divide them into sizes and put them in separate houses. One part of bran and two parts pollard, and double the quantity of finely chopped greenfeed mixed with it and fed three times a day or more if wanted, will be found suitable. As soon as the ducklings are feeding well, a little meat meal can be added to their other food, say, 1lb. per 100 birds. Wheat and barley meal are sometimes used. The Pekin duck has proved most satisfactory in Australia; it is suited for export trade and sells well in England. White ducks are better for table use. Muscovy ducks are the best table birds; they carry plenty of meat, some of the drakes weighing as much as 14lbs. and the ducks about 7lbs. They are easily bred. See that good, dry nests are made for them. The eggs take from 34 to 35 days to hatch. Only ducks two or three years old should be mated with the best procurable drakes. Keep the yards and houses clean and dry; clean out all rubbish and put clean sand all over the yard. A plentiful supply of shell grit, charcoal, or coarse sand will assist in keeping the birds healthy. Ducks are expensive to feed, and at ruling prices it does not pay to rear them. At present ducks are cheaper than butcher's meat. Ducks can be easily plucked if scalded with plenty of water and then wrapped in a bag for 10 minutes. Up to 20 hen eggs can be set under a duck, but the duck must not be allowed near running water when sitting on fowls' eggs.'' (Secretary, Mrs. Robertson.)

WARCOWIE (Average annual rainfall, 11.42in.).

June 17th.—Present: Eight members.

The meeting took the form of a Question Box. ''What can be done to linoleums from which the pattern has worn off to make them keep clean and not show footmarks?'' *Answer*—It is almost impossible to do this, because once the surface of the linoleum is worn it is impossible to restore it, but if the linoleum is thoroughly cleaned and then varnished with a good clean varnish it will greatly improve its appearance. If the lino. is in a very bad condition it may need two coats of varnish, but allow the first coat to dry well before applying the next. ''How to get rid of silver fish?'' *Answer*—Spray the affected places with flytox, and do this fairly often until there are no signs of the insects. ''What causes cornflour sponges to cook nicely on top and underneath form a thick, rubber-like substance? If peeled off while hot the sponge is otherwise nice.'' *Answer*—The cause of this is too cold an oven or because the papers used in the cake tins are too thick.

Mr. C. A. Goddard (School of Mines) spoke to members on the scouring of wool. (Secretary, Mrs. A. Crossman.)

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING 1932.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—10s. per Setting of 15 Eggs; Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—15s. per dozen; £5 per 100.

Free on Rail, Salisbury. DELIVERY, July, August, and September.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Victoria Square, Adelaide.

C. F. ANDERSON, Poultry Expert.

WILKAWATT (Average annual rainfall, 16in. to 17in.).

June 21st.—Present: 8 members.

HOME REMEDIES.—Mrs. A. Young read the following paper:—"To know what to do when a child becomes sick or hurt in games with other children is part of each mother's daily work. Often a child is more frightened than hurt when something unusual happens, but with a nervous child the shock has a worse effect than the actual hurt. A cough, cold, bad headaches, or pains in any part of the body if treated at once by a simple remedy is usually curable, but if left unchecked for any length of time may cause a very serious setback to the child. Should the home remedies not prove effective, it is not advisable to wait too long before consulting a doctor. Irritability is mostly a sign of ill-health, and it is mother's "job" to think out the cause. Perhaps an unbalanced menu has caused constipation or it may be over excitement with insufficient sleep. Plenty of sleep for the growing child cannot be too much emphasised. One trouble in children which could almost come under the heading of maladies is shyness. Great care and gentleness is needed with children who suffer from it. Shy children should never be bullied into doing things, but if they are made to realise that their help is needed to make things a success in helping others, they forget themselves. Always remember the proverb, "Prevention is better than cure;" make the body strong so that there will be plenty of strength to resist disease. If a child needs a tonic, cod liver oil or extract of malt are both good. For constipation, 1lb. of dates minced with 1oz. of senna leaves is excellent, and children take it readily. For eruptions of the skin, ½lb. of sulphur mixed into 1lb. treacle and given freely to children is good. A few drops of eucalyptus in 1 tablespoonful of olive oil rubbed on throat and chest is good for coughs and colds and also for aching limbs, bumps, and bruises. For a scald, the white of an egg (not beaten) applied on a bandage will give instant relief and prevent a blister. *Cough Mixture.*—Boil together 2 cups treacle, 4 cups water, skim and stand until cold. Get from chemist threepennyworth each of aniseed, paragoric, ipecacuanha wine, peppermint. Shake well and put with boiled mixture, bottle. This mixture will keep for months." (Secretary, Mrs. W. Pritchard.)

SPECIAL SESSION FOR WOMEN AT JABUK CONFERENCE.

Delegates and visitors to the number of 72 attended the Special Sessions held for women at the Jabuk Conference in August. Mrs. White and Mrs. Cabot, of the Parrakie Branch, acted in the capacity of President and Secretary respectively.

Addresses were delivered by Miss E. Campbell (Dip. Econ.). of the Education Department, and Messrs. H. B. Barlow and C. F. Anderson, of the Department of Agriculture.

The following papers were read and discussed:—

COMFORTS MADE FROM WOOL PREPARED ON THE FARM.

[By Mrs. WHITTLE, Pinnaroo.]

Take a well woolled sheep skin as soon after killing as possible, lay it out—wool side down—and from the back cut out eight or ten square pieces. Steep these in cold water in which a little soap or soap powder has been dissolved the night previous to the weekly wash day. Wash the pieces well with soap in the last warm rinsing water, blue, then rinse in clear water. If dried with the blue water in the wool it is likely to have slightly stained tips. Hang out to dry, stretched as straight as possible. When dry, clip the wool off close to the skin and spread on trays in a cool oven for half an hour or so. When teased out a little, this makes an excellent filling for pillows, cushions, mattresses, &c.

For eiderdowns and fine quilting, such as dressing gowns, matinee jackets, &c., comb the wool with a fairly wide toothed comb as it is clipped off; the pieces cut from the shoulders are the most suitable for this finer work. The shorn pelt—if slightly tanned—**has many uses, such as a triangular** piece laced over a worn floor polishing mop, **a half circle stitched round and wool filled used as a kneeling pad for floor washing, gardening gloves, and** children's slippers—these are a few of its many uses.

HOME CLEANING AND POLISHING.

[By Mrs. E. J. Sands, Pinnaroo.]

Start the day by pushing the doors and windows wide open, curtains back, and bed tossed up ready to air, then as soon as breakfast is over the rooms are ready for attention.

Washing the dishes is made very easy with a dish mop, hot water, and soap. **A brush** for glass dishes, to brush out all the patterns which are stamped on them. **A separate dish** is needed for silverware with a large flannelette towel to dry it, **give each** piece **a good rub** and it will save a lot of plate polish and give the silver **a soft, smooth** finish.

Always protect beds, cushions, bowers, plants, and ornaments whilst the rooms are being swept. Flowers and pot plants should be removed. Cover as much of the furniture as possible with a dust sheet, made from any patched old sheet. Wash the floors with soap dissolved in hot water, with a few drops of kerosene and phenyle. Kerosene keeps the hands soft, and phenyle is a good disisfectant.

Mirrors washed with whiting in the water will be quite bright if flies are a nuisance; rub, after polishing with kerosene, on a duster. Washing coppers can be cleaned with half a cup of kerosene rubbed around the copper with sheets of newspaper. Rub with

sheet after sheet of newspaper until the copper is quite bright. The blue water will be much easier to manage on washing day if a dipper full of hot, soapy water is added before the blue. Starch will be less likely to form a skin on top if some cold water is added as soon as the starch is made.

If a petrol iron is used, strain the petrol between two thicknesses of silk. Damp the articles ironed with hot water, and they will be ready to iron almost immediately. Coffee with milk stains can be removed with pure glycerine. Brush the glycerine on the spots, wash in warm water, and iron with a warm iron.

To clean a leather coat, wash it over with saddle soap, then paint over with a medium solution of Condy's crystals, and rub over with the white of an egg, then with a dry, soft cloth. Spirits of camphor will remove most marks from polished wood, followed with some good furniture polish on a piece of soft silk. A porcelain sink can be cleaned with flannel dipped in kerosene rubbed on until all stains are removed. Aluminium saucepans should be rubbed well with sand soap. Never scrape or use soda to clean them.

HOME RECIPES.

Mop Oil.—1 cup new linseed oil, 2 cups kerosene; shake well together.

Kitchen Cleansers.—(1) 1 cake Velvet soap, 1 cake sanoper soap, 2 pints water; cut up soap, boil until all the lumps are dissolved. (2) 4ozs. fine sand, or part ashed, 4ozs. salt, 4ozs. whiting, 4ozs. extract of soap; sift together. (3) 2 packets of soap extract, 1 pint of boiling water; 1 bar of sanoper, dissolved together.

Floor Polish.—About 2ozs. beeswax, shredded into 1 pint turpentine, and left for a few days, will make a good floor polish.

Lino Polish.—1lb. beeswax, 9 cups water, 1 quart turpentine, 2ozs. potassium carbonate. Shred beeswax, put with water and potassium into an old saucepan, heat until wax is melted. Do not boil. When cool, stir in turpentine; stir occasionally until thick.

Furniture Polish.—½ pint linseed oil, ½ pint turpentine, ¼ pint methylated spirits, ¼ pint vinegar. Bottle and cork well; shake before using.

Cloudy Ammonia.—2ozs. pure ammonia, 1 pint water, small piece of soap, 1 teaspoon borax. Bottle and cork; shake well before using.

THE VALUE OF LITERATURE IN THE HOME.

[By Mrs. DOWD, Pinnaroo.]

In many homes in the country, and perhaps in the town, one will not find a book—even the daily paper is not taken. A weekly paper occasionally will find its way in. Children, in that home, are not encouraged to read, and in later life novels by doubtful authors, not fit for adults, find their way into the hands of children, because they have not learnt to love and value good literature. A parent can choose a book, and read perhaps a chapter a day to her child, and there are very few children who do not ask for a story on going to bed, and quite a lot of good story books are written. The parent will get as much enjoyment herself out of these stories as the child. When the child grows older and can read—if the parent has not the time to read and choose all his books—for the small sum of 3s. 6d. a year, he can join the Juvenile library in his district—and most libraries have Juvenile books. For that subscription he is entitled to three or four books a week. They have been read by a reading committee and approved of by that body, before being placed on the shelves, and will be all good and suitable books. "Alice in Wonderland" appeals to the youngest child, and can be understood. "No. 1 and No. 2 Jay Street Adventures in Fairyland," by John F. Macpherson; such authors as Doris Pocock, Ethel Turner; The Anne Books, by L. M. Montgomery: "Anne of Avonlea," "Anne of the Islands," "Anne of Green Gables;" Girl Guide Books, School Stories by Ethel Talbot, May Wynne, and quite a lot of other authors are suitable for girls. Books for boys will include "Pirates," by F. G. Bullen; Luke Allen's Detective Stories, School Books by A. N. Malan, Boy Scout Books, George Durston, Adventure Stories by Tom Ellis and Herbert Strang. Mrs. Herbert Strang also writes a good book for girls.

As the children grow older they will subscribe to the Public Circulating Library, and by their books being well chosen in childhood, will know the good books, and will take home books to broaden their minds on some particular subject. People and places that one will never see become familiar through reading about them. It broadens the mind, and provides something for discussion. A child that has been educated in this way in the home, and in the value of literature from infancy, will very seldom get into bad company and trouble. He has been taught to choose his companions through reading of honorable men and women, and is quite content to read and study, whilst others, who have not had this education in the home, will get into trouble and cause their parents much anxiety.

There are many Australian authors with whom all should be familiar. Between 1880 and 1900 there sprang up a school of young Australian writers, who told their own life in their own natural way. The best known writers of that school are A. B. Patterson and Henry Lawson. Between them they sum up the greater part of bush life and bushmen's aspirations. Patterson—his heroes are horse lovers—whose memory recalls the bush at its best, the drover singing behind his stock. Lawson's bushmen are a different class, and the sunlit plains are to them a waste, "where all day long in the heat and dust, when summer is on the track, with stinted stomach and blistering feet, they carry their swag outback."

Edwin Brady did for the shipping folk, and Edward Dyson for the miners, what Patterson and Lawson did for the men who handle cattle and sheep. Since 1900 there has been a marked change in the tone of Australian literature, though from the Lawson and Patterson school sprang "The Sentimental Bloke," of C. J. Dennis; the Australian Irish, "Boree Log," of John O'Brien—both worthy writers. Hugh McCrae stands out for distinction. David McKee Wright, too, is genuinely a poet. Two women writers—Mary Gilmore, the more poignant, and Lora Cross, the more passionate. A third—Dorothy Mackellar—will live by virtue of one poem, "My Country."

The output of prose fiction since 1900 has been great. Among the notables are Steel Rudd's "On Our Selection" and Mrs. Gunn's delightful annals of the Northern Territory, "We of the Never-Never."

HOOK MATS MADE FROM WASTE MATERIAL.

[By Mrs. R. C. KERLEY, Parilla.]

The materials used for this work are sugar-bags, old cardigans, stockings or any soft worn-out material, and a steel crochet hook, the largest size obtainable, or one made from a piece of fencing-wire. Wash all the material and dye it the desired color. Cut into strips from ¼in. to 1in. in width (according to the thickness of material being used) so that it will pull through the foundation easily.

MEGGITTS
LINSEED
MEAL
FOR COWS, PIGS & POULTRY

From a sugar-bag cut it the size and shape required. Tack down all the rough edges, then mark the design distinctly on to the sugar-bag. Place the strips of material under the foundation and pull through with the steel hook to about ½in. high. Continue this method as close as possible, working the colors into the pattern as desired. When the whole of the foundation is covered, clip off with sharp scissors. These clippings can be saved for filling mattresses, cushions, &c. Line these mats with hessian or sugar-bags. If desired, a fringe can be made of wool on each end of the mats. Always start at the centre and work outwards; this makes the work much easier to handle.

PUFF PASTRY.

[By Mrs. C. BROWN, Parilla.]

When making puff pastry, everything must be kept cool and made as far away from the kitchen fire as possible. The oven must be the correct temperature; if too hot the fat will ooze out, and if not hot enough the pastry will not rise as it should. To test the oven, sprinkle a pinch of flour on the tray, close the door, and count 30 slowly; open the oven, and if the flour is a nice golden color, the heat will be right. Pastry should be mixed with just enough cold water to make a nice pliable dough, and it should not be too moist nor too dry. *Ingredients.*—12ozs. plain flour, 12ozs. margarine, or 6ozs. each of butter and lard, cold water to mix, and a pinch of salt. *Method.*—Sift flour and salt into a large basin, and with a knife mix with the cold water into a nice dough. Turn out on to floured board—a marble slab if possible—roll out fairly thin, always rolling from you. Divide the fat into three portions; place one portion on dough, fold into three towards you, and then roll out thinly. Leave for 10 minutes, and place on second portion of fat, fold and roll as before. Leave again for 10 minutes, then place on third portion of fat, fold and roll again as before. Leave for another 10 minutes, then fold in three and roll three times more, rolling the last time to thickness required.

RECIPES.

Jam Tarts.—Roll pastry out to about ½in. thick, cut out with tart cutter, glaze with beaten egg, and bake 10 minutes.

Maracoon Tarts.—Roll out some pastry fairly thin and line some pattytins with it, then place 1 teaspoonful raspberry jam in bottom of each, then fill with the following mixture:—4 tablespoonfuls cocoanut, ¼ cup sugar; mix well with 1 beaten egg.

Banbury Tarts.—Roll pastry fairly thin, spread the following mixture on one half, fold the other half over, wet edges and press together; roll lightly with rolling-pin, glaze with egg and sprinkle with sugar. Mark into squares, and take 10 to 15 minutes. Mixture for filling—Mix well ½lb. currants, ¼lb. sugar, 2ozs. chopped peel, 2ozs. butter, and 1 teaspoonful cinnamon.

Jam Turnovers.—Roll pastry fairly thin, cut into rounds with small saucer. Place a spoonful of jam in centre of each and fold the three sides over towards centre, making a triangle shape. Glaze with egg and sprinkle with sugar. Bake about 10 minutes (Mrs. Brown exhibited tarts, &c., made with margarine.)

THE USE OF LEMONS.

[By Mrs. F. W. GRAVESTOCKS, Parrakie.]

The housewife will find lemons very useful in many ways in the kitchen, especially in summer, when a cold lemon drink is very acceptable. A hot lemon drink in winter is also enjoyable, and as a medicine they are unsurpassed. The juice of three lemons "undiluted" and without sugar will generally stop vomiting, and for weakness after sickness a patient will be able to take—and also keep down—a tablespoonful of brandy and the juice of a lemon. The juice of a lemon added to the blue rinsing water when washing white silk will keep the silk pure white instead of turning yellow. A few slices of lemon added when boiling clothes helps to keep them white. Stains on the hands can be removed by rubbing with lemon. When aluminium pans become black and dull, clean them with a soft cloth dipped in lemon juice; rinse in warm water.

To freshen stale vegetables, soak them for one hour in cold water to which the juice of a lemon has been added. When cooking prunes, add the juice and rind of half a lemon. To remove iron rust quickly and easily from any material, invert a medium-heated iron, place on it the stained fabric, and gradually squeeze the juice of a lemon on the stain. The mark will be carried off with the steam. For removing verdigris from a copper, lemon is excellent. Slice three or four lemons and put into the bath water until the juice is extracted; they impart a delightful sense of freshness and cleanliness to the skin. A few drops of lemon juice on the toothbrush will keep the teeth perfectly white. Lemon juice makes an excellent substitute for shoe polish. A few drops rubbed briskly on black or brown shoes imparts a brilliant sheen. Lemon peel thoroughly dried and ground to coarse powder is very good for flavoring biscuits and small cakes, puddings, &c. A teaspoonful of spice added to a hot lemon drink will "break" a cold very quickly. After taking the drink it is advisable to go to bed immediately owing to the excessive perspiration caused. Lemon juice in hot coffee will help to relieve a headache. When washing the hair, add the juice of a lemon to the rinsing water. Lemons can be made into very nice jam and jelly, and many different kinds of jam may be improved by adding lemons or juice. Candied lemon peel can also be made. Lemons keep much better if put into a string bag and hung in a cool airy place.

● **FULL MOON.**

HANDY HINTS FOR THE HOUSEWIFE.

If in doubt about mushrooms, sprinkle the under side with salt and leave for a few minutes. Those which turn black with this treatment are wholesome; those which turn yellow are poisonous. Talcum powder will remove grease marks from delicate fabrics. If a little kerosene is mixed with aluminium paint before it is applied to a cold stove, the paint will better resist the action of hot liquid. Use thick boiled starch to paste covers on jam jars; smear over the whole of the cover when dry—it will be stiff like parchment, and so prevent the entrance of damp.

When eggs are scarce, remember that in a cake or pudding mixture 1 tablespoonful of golden syrup dissolved in ½ pint of warm milk will equal three eggs. When making starch on washing day, add 1 cupful to the blue water; it will not make the clothes stiff, but they will dry in half the time. If when making a fruit cake the top of it is patted with a wet hand after it is placed in the tin, it will not rise higher in the centre than at the sides. Blankets dry much more quickly and are softer if they are only lightly hand-wrung, pegged on the clothesline, and allowed to drip until dry. Cold tea is an excellent first-aid remedy for burns. Save the flaps from unsealed envelopes which enclose circulars, &c. Being gummed, they are handy to make small labels for containers. Do not wear gloves when cleaning garments with petrol; the spirit will cling to the hands and the skin may be badly scalded.

HOME-MADE BREAD.

[By Mrs. J. A. FERME, Parrakie.]

Having made bread continually for over 30 years, the following method has proved simple and effective. My yeast bottle was started with hop yeast, which is most satisfactory for both summer and winter. *Method.*—A small pinch of hops in a basin; pour on ½ pint of boiling water, stand until lukewarm, strain into the bottle, add 3 teaspoonfuls of sugar, and slice or grate a raw potato into it. One tablespoonful of beer will start the yeast for the first time, or a small piece of dough from a neighbour's baking or a drop of her yeast. Do not tie down the cork, and as soon as the yeast comes to a head, make the following sponge:—Take 4 sifters of flour in the breadpan, make a well in the centre, pour in the yeast and lukewarm potato water, water saved from potatoes boiled for a meal, or boil a potato for the purpose. Make a batter and lightly turn the flour from the sides over the top, sprinkle on handful of salt when risen. Mix with warm water into a fairly stiff dough, put into a warm place, well covered, to rise. In summer, cold water to mix the sponge and prevent sourness and other unpleasant odours. When the bread has risen to the top of the bread pan, take and roll small loaves between the two hands, and put into well-greased bread tins and again set to rise well. Then bake for 1 hour in a fairly hot oven. Be sure to bake well; keeping and cutting qualities depend on well-baked bread.

RECIPES.

Buns.—Take a piece of dough from the bread after it has well risen, and melt 2 tablespoonfuls of butter; add 3 tablespoonfuls of sugar, 1 egg, also a few currants or sultanas. Mix well, work into small buns, and put on a greased slide; set to rise until bread is baked. Bake quickly, then paint over with 1 tablespoonful of sugar and a drop of boiling water, while still hot.

Yeast Cake.—Add 1 cup of milk to the same mixture, also a little nutmeg, and put into a greased cake tin to rise. *Top for the Cake.*—½ cup of flour, ½ cup of sugar, and a little melted butter. Add cinnamon and crumble together; sprinkle over top of cake before baking.

Hot Cross Buns.—Ingredients.—1 pint of good yeast, 5ozs. margarine or butter, 1 teaspoonful of ground cinnamon, ½ level teaspoonful of grated nutmeg, ¼ teaspoonful (level) of ground cloves, ¼ teaspoonful (level) ground ginger, ½lb. crurants, 1 egg, 5ozs. of castor sugar, 1½lbs. of flour, ¼lb. mixed peel, ¾ pint of milk. *Glaze for Hot Cross Buns.*—6ozs. icing sugar, about 2 dessertspoonfuls of milk. ***Method.***—Sift 4ozs. of flour into a large basin, strain in yeast, mix to smooth batter, cover basin and set to rise in a warm place for about 1 hour. Meanwhile wash and pick over and dry the fruit and shred peel, sift the remainder of flour into another basin with the spices. Rub in fat, add sugar and prepared fruit, and mix together well. When the yeast mixture is ready, stir into the other prepared ingredients, adding also the beaten egg, and the remainder of the milk made warm. Mix altogether and beat well. Put the mixture in a warm place to rise until it swells to double its bulk. It will take about 2 hours. When the dough is ready, work into 36 small buns. Place the buns on lightly greased and floured baking-sheets, leaving a space between each to allow them to rise and mark a cross on the buns. Stand buns in a warm place to rise another 20 minutes or until double their size. Put them into a fairly hot oven to bake for about 20 minutes. Brush over the hot buns with the glaze and put back into the oven for 1 minute to dry.

Pig Keeping.—Mr. J. Ryan, in the course of an address on this subject, first dealt with the origin and development of the present-day pig—the various types and the characteristics of each, including such well known breeds as Berkshire, Large York, Tamworth, and Mid York. In a test in Canada of 2,000 pigs these four breeds had proved most successful. For a farmer going in for pig keeping he would not recommend

MEGGITTS
LINSEED
MEAL
FOR DAIRY COWS

pedigreed stock for a start. Berkshire x Tamworth sow to Large York boar would give good results to the beginner. In regard to farrowing he did not favor placing the sow in the farrowing pen until about a week before due, neither did he favor sloppy feed for the farrowing sow. He recommended tying and dressing the navel strings of the piglets if the sow was quiet. Castrating could be carried out at four weeks, and the suckers weaned at six or preferably eight weeks. They could be dosed for worms at four weeks if necessary—one teaspoonful of turps for each month, given in milk for three days. In the case of a young sow with her first litter it was advisable, if the litter was a large one, to pick out six or eight and kill the balance. The ultimate result of this would be more profitable than if the full litter was left for the sow to rear. A sow should not be mated under eight months, preferably not until 10 or 12 months. In choosing a young sow for breeding purposes select one with not less than 10 teats, and also from a large litter if possible. In feeding pigs, he favored the dry method. He had got good results from scattering the whole grain on the ground. The pigs would pick up every grain and would not bolt it down as they would if fed from a trough. If it was desired to soak the grain it should be soaked for not less than 30 hours. Milk, of course, was one of the best possible feeds for pigs, either sweet or sour, but it should be given always sweet or always sour; never change about or serious trouble would result. Peas, too, were a valuable feed, but should be fed sparingly—about 25 per cent. of the total ration. Meat meal could be used as a substitute for green feed and milk. Of the green feeds, lucerne was easily the best. Artichokes were a hardy plant and he had fed them with advantage when nothing better was available. The quantity of feed for a growing pig was about 5lbs. for every 100lbs. weight. *Diseases*: The biggest pest in connection with pig diseases was worms, particularly the long round worm. These worms harbored in the intestines of pigs, and the embryos or young worms passed through the wall of the intestine and were often the cause of thumps, malnutrition, &c. One of the best anthelmintics for ascarides was oil of chenopodium—the dose being 4 cubic centimetres for a 75lbs. to 100lbs. pig given in 1oz. of castor oil; each pig should be fasted for 24 hours before being given this medicine. Asked if it was detrimental to the pigs' welfare to place rings in the nose, Mr. Ryan replied in the negative, and said the pig would not lose weight. Another method was to split the cartilage, this was very effective, but the advantage of the ring was that if desired at any time to allow the pig to root the ring could be removed. Two or three rings could be put in and if one got torn out it would save catching the pig again. In reply to Mr. Manning, Mr. Ryan said that it was most important to choose a breeding sow from a large litter, his experience had proved that, and it was more important still in the choosing of a boar. In reply to a question *re* castrating, Mr. Ryan said he always placed the pig in the recumbent position. Mr. Manning favored holding the pig up by the legs. Messrs. Dinning and Hunt also favored this position. For a dressing after the operation Mr. Ryan said Flint's oil was one of the best. Mr. Manning used kerosene, Mr. F. Dinning used white pepper, and Mr. Packer oil and eucalyptus. Mr. Warland inquired if rabbits were good pig feed. Mr. Ryan said he had used them to advantage, but they should be well cooked, as they were often affected with hydatids. (Secretary, A. Ross.)

MONEY AND CREDIT.—Mr. V. Knauerhause read the following paper:—"The study of money and credit is a fairly small, but very important branch of economics, and the monetary system is the basis of our present-day economic structure. By the economic structure of a society or a country is meant the system by which the members of that society are able to exchange the goods they have for the goods which they require; the system by which they are able to sell the products they have either grown or manufactured, and buy with the money obtained the articles they require—groceries, clothing, implements, &c. On the surface, it might seem as though this system is simple enough, but when we begin to inquire into the nature of that system we see what a complex thing it is. As an example, take the management of a farm. The farmer is able to grow his own wheat, produce his own meat, milk and butter, eggs, and vegetables. It might be thought that he could be quite independent of others in the society or country in which he lives. But under the present complex system of the exchange of goods it is impossible for him to remain quite independent. It is true that he is fairly independent compared with the person living in the city, but nevertheless, he looks to others to supply him with many of his necessities. To take a simple example, the farmer sells his wheat. With the money he receives he may go to the stores and buy flour, groceries, and clothing, from the manufacturer he may get manure for the next season. If, after he has made these purchases, there is still some money left, he may buy some other necessities or bank his money. It should be noted, however, that in this discussion of the farmer' activities, we have supposed that there is some sort of economic structure in existence. In the first place there is some system of money and banking; in the second place we have supposed that the articles which were required were ready at hand in the grocer's shop. But the grocer himself had to buy the flour from the miller; he had to import the spices from overseas; he had to get some of the clothing probably from England. Then we should notice again that there must be mills to grind the flour, plantations to grow the spices, factories to produce the clothing. Further, we should notice that before the goods can be brought to the grocer there must be adequate shipping and transport facilities; and above all, there must be some banking system by which payment can be made for the goods or for transport. It will clearly be seen from this discussion that the economic structure at the present time is very complex. How complicated the whole system is may be seen also from the fact that although conditions are so bad generally and many people are either unemployed or nearly bankrupt, nevertheless there is a surplus of many different products, there is a surplus of wheat, coffee, clothing, and machinery, &c. There is no shortage of produce nor manufactured goods; there is only a shortage of money among the general public. It may be seen from the foregoing discussion that if we merely perform the simple act of buying a pound of tea, we take for granted that there are already in existence plantations, factories, transport facilities, and money. It should be noted, however, that purchases were not always effected as they are at present. At one time all trading was done by means of barter. This system is still resorted to by small boys when, for instance, they agree to "swop" 10 marbles for a spinning top or something like that. At one time all exchange was effected in this way. A person having a hundred bags of wheat would try to find someone with a package of clothing; he would then exchange some of his wheat for some clothing. It can easily be seen what a difficult business it would be to decide how much wheat should be given for so much clothing. Perhaps one man would have a surplus of wheat and then he might be willing to take pieces of gold or silver in exchange for his wheat, and when he wanted some tea, for example, he might find that the tea merchant would accept gold in exchange for tea. This is the beginning of the money system by which goods are no longer exchanged for goods, but for some medium of exchange, which is called money, and which in this case is gold and silver. A very important point to notice about money is that it has no value except as a medium of exchange. Of course, it is an advantage to use as money such things as gold or silver, which have a value apart from their value as money, but it should be noticed that pieces of lead or even stones could be used as money provided everyone in the community were willing to accept them as payment for their goods. I make a distinction between money and credit. By money is meant the gold, copper, and silver coins in use, and perhaps banknotes. By credit—cheques, bills of exchange, bank drafts, &c. Our monetary system in Australia, then, consists of gold sovereigns, silver and copper money, and banknotes. The basis of this system is the gold sovereign; the silver, copper, and banknotes receive their value from the gold sovereign. Thus by law it is fixed that no matter what value the silver or copper may be, 20 shillings and 240 pennies may always be received in exchange for one sovereign. The value of a banknote lies, really, only in its promise to pay gold to the holder; hence will be seen on each banknote the promise that gold coin will be paid if the note is handed in at the Sydney branch of the Commonwealth Bank. This, of course, is not true at the present time, but it has no effect upon the value of the note, since anyone in Australia will give 20 shillings in exchange for a pound note. At the present time credit has largely supplanted money as a medium of exchange, and it is for this reason a more important subject. The credit system depends upon the existence of banks, and it will be interesting to inquire how the banks came into existence, say, in England, for example. In England the jewellers began the banking system. These jewellers had strong iron safes to guard their supplies of gold, and so anyone having a few gold or silver coins in his home would take them to the jeweller, for they would be safer in his strong-room than at home. After a time the jeweller would have a considerable amount in his safe. Let us suppose that A owed B £5 and that both had dealings with the jeweller. Then instead of giving A 5 gold coins with which to pay B the jeweller might give A a signed slip of paper promising to pay the holder 5 gold coins when

it was handed back to him. A could give this slip of paper to B and B would take it to the jeweller. This was the start of the modern cheque system. Again, the jeweller might issue notes promising to pay the holder in gold coin. Further, he might find that he had in his vault a considerable amount of gold, say £50,000. He would lend some of this money (always keeping a reserve) to his clients at a fixed interest. At this stage the jeweller would be a banker doing exactly what the banker does at the present day. There is one point of interest in connection with banking which everyone should know, especially as it has been considerably in the foreground during the last few years. It is a fact well known to all that during the last few years money has been very "scarce"; the banker is not willing at present to advance money or credit, except on good security. It is interesting to see why this is so. In describing the jeweller I mentioned that he would lend money on interest, always taking care that he had an adequate reserve of gold. It has been found by experience that only a certain proportion of the money lent is necessary as a gold reserve. In general it has been found that about four times as much money may be lent as gold is held in reserve. Let it be supposed that a person goes to the banker for a loan of £100; notice that the banker does not possess this money; he creates or manufactures the money, or really, credit. What happens is, in effect, this: The banker says, 'You use our cheque books and if a cheque from our bank signed by you arrives here I will pay the holder in banknotes or silver, provided the cheque does not exceed £100. But the banker cannot continue to lend out money on credit in this way because if he did so he would soon have far too much money on loan in proportion to the amount of his reserve. Hence, after the banker has lent out a certain amount of money he begins to restrict his credit; he is no longer willing to lend money to clients except on very good security. The banker may even wish to reduce the proportion of credit to that of his reserve; in this case he might demand the payment of loans and perhaps refuse credit altogether. This process is, in effect, exactly what the bankers have been doing during the last few years. Another point should be noted in connection with the manufacturing of credit. Let us suppose that A owes B £50 and that they both deal at the same bank. A may go to the banker and get a loan of £50. Under ordinary circumstances the banker will manufacture or create this credit. A may now pay B with this money and B will, let us suppose, pay this amount into the bank as a deposit. Notice what has happened: The bank has created £50 credit, and since B has paid it into the same bank as a deposit the bank has become liable for £50 and this money is, in fact, not real at all. *Foreign Exchange*: It might not be generally known that all imports must be paid by exports; hence, if machinery and clothing are imported from England to Australia the only way in which Australia as a country may pay for these goods is by exporting to England some of her products, such as wheat, wool, frozen meat, fruit, or gold bullion. One very important factor influencing the rate of exchange between two countries is the balance of indebtedness between those countries. Thus, if Australia has imported more goods from England than she has exported to England the balance of indebtedness will be in favor of England, and the rate of exchange will be unfavorable for Australia. Since all debts to foreign countries must be paid through the bank, the bank is able to control the rate of exchange. This is what is happening in Australia at the present time; the rate of exchange is fixed by the bank. Let us suppose that the rate of exchange is such that £115 must be paid to the bank here to pay a debt of £100 in England. That means that for every £100 worth of goods imported we must pay £115, and that for every £100 worth of goods exported we receive £115. It follows from this that in such a case it is advantageous for Australia if she exports and not advantageous if she imports. Suppose that the rate of exchange goes up from £115 to £120 for £100. The value of our exports will be increased in proportion, and in particular the price of wheat will rise. The economic system of the present time is very complex, and is in the main possible only through the credit and banking system. Money need not necessarily have, but usually does have, a value apart from its junction as a medium of exchange. Imports from a country are in general paid for by exports to that country. And finally, if the rate of exchange becomes more unfavorable for a country the value of its exports is increased.'' (Secretary, S. C. Rooke.)

YANDIAH.

June 10th.—Present: 14 members.

Care of the Breeding Ewe.—The following paper was read by Mr. A. R. Keller:—"Owing to the dry seasons that have been experienced, flocks have been greatly reduced, breeding ewes are in great demand, and on that account one does not advocate heavy culling when selecting the ewes for breeding. Old ewes are the best mothers, provided they are still sound in constitution. At shearing any ragged or poor fleeces should be rejected and a mark put on the sheep, and after shearing a thorough inspection would be necessary to cull out any that are getting faulty in the mouth. About the middle of October the rams should be joined; about 2 per cent. should be sufficient, but 3 per cent. is preferable in order to have the lambing period as short as possible. Then the lambs would be more uniform in size, which is an advantage at tailing, because most of them could be done on the same day when four or five weeks old. There would then be no need to keep the sheep confined to the same paddock for very long, and they would benefit by a change. March is the best time for lambing; the two extremes of the seasons, the heat and the cold, both are disastrous to young lambs, and the weather at this time should be between the two. At this time there should still be good dry feed about, grass or stubble, as a month later might see the dry feed spoilt by a rain, and no green feed available. As it is mostly Merinos that are handled, the March lamb might not grow as quickly as a June lamb, yet at shearing the difference in the quantity and quality of the wool from the two lambs would be quite considerable. The early lamb if well grown would breed the next season. Before lambing, ewes should be crutched and separated from the other sheep if possible, and put into a good paddock that has been saved for them. It is very important that the flock is quiet, because at this stage they need a lot of attention, and if you can afford the time, take a walk round them every day, because there may be some that need assistance. If the young lamb seems weak or does not feel inclined to get up, as long as the mother stays with him do not interfere. Keep the dog at home when making the rounds, even if the sheep are used to it. An old ewe becomes irritated if the dog tries to get close to her, and she gets bold enough to attack any dog; as the lamb gets older she becomes less furious, but this bad habit is very annoying, and might spoil a good dog. The young ewe, on the other hand, becomes timid at the sight of the dog, and might desert the lamb, and if she does return to him later, she may find that her offspring has already fallen a prey to hawks or crows. If the season is dry, start hand-feeding before the paddock gets bare. A home-made self-feeder is best for economical feeding. A simple method of feeding is with sheep nuts, as you only need to put them on the ground; but that class of feed is too expensive when fed by itself, and if not enough is given, the sheep are not satisfied, and will wander about too much. The best feed for the ewe is either bran or oats mixed with hay chaff." (Secretary, F. L. Jettner.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

GREENOCK.

May 23rd.—Present: 38 members.

The Hon. Secretary gave an address and demonstration of Vine Pruning. Mr. W. Roenfeldt reported on his fertiliser experiments with cereals and vines.

Seasonal Report on Vines.—The following report was read by Mr. A. Schubert at the April meeting:—"Rainfall in this district is of the utmost importance for the vine grower, because he depends entirely upon rain for moisture. Rainfall for 1931 was nearly 20in., 2½in. above 1930, but still 1½in. below average. Winter was considerably wetter than the average season, and by the end of April the fall was 1in. below the average, and by the end of September more than 1¼in. above average. Only 1½in. were received the last three months, whereas usually more than 4in. are received. Winter being so wet, pruning was left a little later than normal. July and August are generally considered the best months for pruning vines. The strength of the vines and soils should always be considered when pruning; the pruner should err rather in giving too little wood than too much. It will be necessary to use some preventive for black spot on those vines subject to this disease last year. Fertilising the vineyards should receive much more attention and thought from every grower. Ploughing is important and speed should not be sacrificed to thoroughness and depth. September is usually considered the best month for ploughing. The first week in September was too wet to think of ploughing, yet after a week in which strong, drying winds were experienced, the ground in most cases was too hard to plough. During the last week of September ½in. to 1in. of rain fell. The ploughs were again set going, and nearly all growers finished ploughing. If there had not been the fear of frosts it would have been wise to harrow and cultivate at this time. However, fears of a further frost were justified, and on the first Sunday in October another frost was recorded. This was more severe than the first, and although this district did not suffer as much as Light's Pass and Barossa, nearly every grower lost an acre. October proved very hot and dry, only a few points of rain, and in most cases it was impossible to harrow or cultivate, the moisture evaporating very quickly through the rough ground. Vines made a very vigorous growth and were showing a good crop, except the frosted areas; these set very few bunches. November was rather cold and misty, but no rain fell. The weather was rather adverse to flowering, although generally the berries set fairly well. At this time thrips were doing damage in other parts of the State, but in spite of them being noticed here damage was practically nil. Rutherglen fly was in evidence in some gardens, which were rather dirty. The first week in December brought a welcome rain, but unfortunately was very patchy, Greenock recording only 10 points, the most neglected gardens at last being worked either with the cultivator or harrows. December proved very hot, and the whole of January still hotter, the thermometer hardly leaving the century mark. Vines were very distressed. The berries were very small and apparently lifeless. In February a general rain of about 1½in. fell throughout the district. Grapes doubled in size within a week, started to ripen nicely, and the weather kept cool, cloudy, with mist right through the month. Finally the vintage proved to be much better and heavier than anyone had dared to hope, and, with but one or two exceptions, every grower had considerably more than the last few years. However, there is for some growers another trouble, and in some instances a serious loss. Owing to a very wet April mould developed in Grenache and Doradillos. Unfortunately hundreds of tons were lost by unfortunate growers.'' (Secretary, H. Wilksch.)

PENWORTHAM.

May 26th.—Present: 15 members.

SIDELINES.—Mr. J Allcock read the following paper:—''Sheep at the present time offer the greatest possibilities. They are almost essential as a means of keeping fallows clean and providing the home with meat. There is a big margin between killing your own mutton and buying from the butcher. In this district fat lambs are more profitable than wool, if worked on the right lines. The average Merino fleece weighs about 9lbs. to 11lbs. This, with wool at an average price of 8d. per lb., would net 6s. to 7s. 6d. per fleece, and a fat Merino lamb would be valued at about 12s. If one went in for fat lambs, wool would be a secondary consideration. I favor the Merino ewe crossed with the Dorset Horn ram and the progeny crossed back to the Southdown ram. This ewe (Dorset-Merino) is the best mother procurable; she is a fine, big, robust ewe, and would rear two lambs a year and do it well. This type of ewe would cut between 7lbs. and 9lbs. of wool; valued at about 6d. per lb., would return about 5s. for wool. When it is realised that this ewe will rear two lambs valued at 17s. 6d. each, and wool 5s., a total of £2, against the Merino total of 19s. 6d., it will be agreed that the crossbred is a better proposition. Another factor that is not taken into consideration generally is the blowfly pest, the crossbred not being so subject to the fly as the Merino, because the former does not carry so much wool and wrinkle around the breech. I favor crutching three weeks before lambing starts, then spraying with a good arsenical preparation. Good results have been obtained with Cooper's dip mixed at double strength 1 in 65. Lambs should be tailed at the age of three weeks. Poultry is a sideline that could be vastly improved on the majority of farms. If farmers could be induced to obtain a good type of bird and look after them, egg returns would go up by leaps and bounds. I favor the Black Orpington as the best utility fowl, and second only to the White Leghorn as a layer. Farmers should obtain 50 chicks from a reputable breeder as the foundation of the flock. Eggs from these birds should average at least 9d. per dozen, and show a return of 15s. per year per hen. Most farms could run at least 100 laying hens, and managed properly will show the pleasing returns of £75 per year. This is obtained with the least labor attached to any sidelines. *Pigs.*—The pig market makes such sharp fluctuations that it is difficult to forecast the future of this sideline, but all should carry on in the hope of better times. Of the four breeds most favored—Berkshire, Tamworth, Large White, and Middle Yorkshires—the Berkshire should be set aside because of their small litters, but crossed with the Tamworth sow it produces an ideal pig, with the possibility of a larger litter. Large York produces large litters, but one does not get that compact sucker that commands attention in the sale ring. A farmer should be able to keep four breeding sows, and if of the right type that will rear 10 pigs at a litter, they should at least pay for feed. The sows rear 10 pigs at each litter and have two litters a year, and these realise 10s. per head at six weeks old, the return will be £40 from four sows each year. *Dairying.*—Under present prices I believe the dairying side of farming is the hardest work on the farm for the amount of cash obtained. The returns come in once a fortnight, bringing in a little ready cash but if men folk on the farm had the work to do that cows entail, very few cows would be kept on the farm. I favor a cow that will put cream in the can, and when she is no longer wanted for this purpose, return a good cheque when sent to the butcher. For this purpose the Friesian fills the bill better than any other breed. The cows should make at least 300lbs. of butter per year, which would return about £19, and averaging the calves at £2 (excepting the Jersey) would bring it to £29 per cow. If the farmer could carry 10 cows, they would net him roughly £200 per year.'' (Secretary, A. Jenner.)

BOORS PLAINS.

May 5th.—Present: 12 members.

COLT BREAKING.—Mr. C. Rodda read the following paper:—''Colt breaking on the farm is an important job and should be treated as such, because the whole of the horse's future behavior depends greatly on the handling it receives during the first few weeks. A man must have several years' experience with horses before he can successfully handle colts; one colt may have quite a different temperament to another, and therefore need different treatment. *Handling Draught Horses.*—The first thing one should aim at is to gain the confidence of the horse, and the younger the horse the easier this is to accomplish. For catching a colt, a small round yard is better than a square-cornered one; in the latter a horse may turn around quickly and have a man cornered. Have the colt in the yard by itself and with a light stick, about 6ft. in length, rub him over the back and get him to nearly face you, standing a little to the near side. Keep your eye fixed on the colt's eye and talk to it in a quiet but commanding voice, and with your right hand move the stick over his back and wither, and try gradually to get close enough to rub his neck with your left, all the while watching his eye. Some colts may need the whip to stop them from continually turning their heels towards you. After you can get your hand on him, try to put on a halter by holding the head strap and putting it over his neck at the wither and working it forward. Hold it with both hands and quietly put it over his nose. With some colts it is necessary to first put the rope around the neck, tying it with a bowline knot, and fixing it to a post to fix on the halter. In tying up a young horse for the first time or two, always put on a body rope and use the neck rope merely to steady the head. Pass both ropes through the back ring of the halter and keep the body rope a little tighter than the neck rope. This is very important, because the colt generally gives up pulling quicker and does not injure or make its neck sore. There is no need to have separate ropes if you have one good long one. Leave the colt tied up for several hours and put a bit in its mouth to allow it to become accustomed to it. Have a look at short intervals to see that he is not hooked up in any way, and talk to the colt for a few minutes while rubbing your hand around its head. The next job is teaching him to lead. Use a strong, light rope, and if you use it double, always fasten the middle of the rope on to the bit, then you have no join in the end of the rope, which would be very dangerous if the colt gets out of control and you happen to get the rope around a leg or arm. Pull the colt around in the loose box or yard, and teach him to come around to both near and offsides. When taking him into a bigger yard, have extra assistance on the rope, because he will try to regain his freedom the first time he is taken out, and if he does so, the longer it will take to teach him he is not the master. If you are short-handed, it may be an advantage to also use a body rope, thereby keeping his head down and making him easier to control. No set rules can be laid down for teaching to lead; there are several different methods which suit different horses. Many will come to lead quickly by one man following with a whip and making them circle for a while, then taking them on the straight. Keep well back unless the colt stops or hangs back, when a smack with the whip will generally help. Another method which works on many colts is the breeching rope. Procure a good, light rope about 25ft. long, double it, and pass an ordinary bit ring over the double end. Put the loop over the horse's rump, letting it hang down to the breech, and with the ring on the horse's back, pass the single ends through each bit ring. Then standing 2yds. or 3yds. in front, keep a tension on the ropes, pulling harder on one, then the other, and the colt will generally soon follow. If a colt sulks and will not lead with the breeching rope, give him a good whipping, and immediately tie him up to a handy post and leave him alone for a while. Then taking him quietly, try leading him again, and this method will seldom fail. To teach the colt to lead while walking alongside, as is done with show horses, needs much more time and patience, but is unnecessary for general farm horses. The next thing is to put the colt into harness. I recommend first putting him in a spring trolley with a quiet horse, unless the wagon is being used, where the colt can be put in the body of the team. When harnessing, always have good, strong harness, and leave the halter on. Take out the bit and put on the winkers over the halter, and there will be no danger of breaking or pulling off the winkers. Use a bit strap in place of a snap on the bit ring. See that the collar is a snug fit; have it a bit tight rather than at all loose. If you have not much assistance, tie up the colt to a convenient post to hook him in for a start. Always use a neck rope until the colt is broken in. If you have no assistance to hook him in the team, put him between two quiet horses and drive them around until the colt finds he cannot get away. For team work first put the colt on the near side of the body of a tandem team, putting him in further after a few times. The near side leader should be staunch in case the colt tries to hang back. Care should be taken not to try and turn the team short until the colt learns how to do it. Only work the colt a few hours for the first day and not more than half days for some time, working according to the age of the horse and strength. Always feed colts well and treat them quietly and kindly, and have plenty of patience, but be firm to let them know who is the master. I believe in handling colts right from foals, teaching them to lead and tie up; then by handling them a little once or twice a year they are ready to harness up whenever they are wanted. The best time to break them in to work is before seeding or during spring, because there is generally more time to devote to them during those periods. Start them working at about 2½ to 3 years of age, but be careful not to overwork them until they are properly hardened. If you do not overload the team, well grown colts at 2½ years soon harden and can stand constant work. The harvester is a good place to quieten them. Colts learn as much in three or four weeks in the harvester as they do in nearly all the rest of the year's work, but they need to have had a few "hooks in" a team before, so that no time is lost with them when you are busy. Look upon the horse as a friend and treat him accordingly." (Secretary, S. Chynoweth.)

WESTERN DISTRICT.

GREEN PATCH (Average annual rainfall, 26.56in.).
May 19th.—Present: nine members.

Silage.—Mr. H. D. Adams (District Agricultural Instructor) tabled a specimen of silage made by Mr Jericho, of Yallunda Flat. He then answered several questions on the making of silage. In a discussion on poultry, Mr. Rieskie stated that fowls must be warmly housed. If not they used up much of their food in keeping up their temperature. He stated that fowlhouses must be kept clean and should be sprayed at least once a fortnight to keep down lice, red mite, and tick. He used a mixture of kerosene and used crank case oil, and found same effective. *Vegetable Red Mite.*—An insect that was making vegetable gardening almost impossible in the district was, Mr. Rieskie stated, being checked in Port Lincoln by spraying with a mixture of kerosene 1 cup, 1oz. washing blue, to 8galls. of water. *The Chronicle Competition for Sidelines on Eyre Peninsula Farms.*—Mr. Adams explained the competition. Members thought it was an excellent move, and it was resolved to pass a vote of appreciation to the proprietors of the *Chronicle* for such practical help and encouragement to the Peninsula farmers, and the opinion was expressed that the competition would be of great value to Eyre Peninsula. (Secretary, T. Whillas.)

POOR CROPS A SOIL ROBBER.

It does not seem possible that poor Crops should be harder on a Soil than good crops, but, according to Scientists, it is so

WHY POOR CROPS CONTRIBUTE TO POOR SOILS.

1. Poor crops develop greater soil erosion.
2. Permit leaching of plant nutrients from Soil.
3. Lower organic content of Soil.
4. Lessen bacterial action.

WHEN GOOD CROPS ARE GROWN.

1. There is a great volume of roots and other residue left to be incorporated in Soil.
2. When crops are well Fertilized, and high yields produced, in balanced rotation, organic content of Soil is maintained even though the normal amount of crop is removed.

A POOR CROP LEAVES ONLY A FEW HUNDRED POUNDS OF ORGANIC RESIDUE.
A GOOD CROP LEAVES TWO TONS OR MORE TO ENRICH THE SOIL FOR NEXT CROP.

GROW THE "GOOD" CROP WITH TOP BRAND
SUPER AND LEAVE YOUR SOIL ENRICHED.

SEEDING OPERATIONS.—Mr. J. Dyke read the following paper:—"In preparing for seeding it is as well to overhaul the drill or combine, unless this was done at end of last season's work. In getting either machine ready for use, first see that all bolts and nuts are tight and replace all badly worn parts; too much play in bearings is likely to cause breakages, and these cause delay in getting on with the work. Also, clean the stars in the manure feed if necessary and paint over with kerosene, and they will be less liable to clog if slightly damp super is used. It is also a good plan to paint the inside of the grain feeders with kerosene, which will counteract the effects of dry pickled wheat, or as an alternative, paint them inside with thin blacklead, and during seeding every now and then paint the grain feeds on the outside with oil thinned down with kerosene or used crank case oil, because all pickled wheat is apt to corrode the wheels in the grain feed cups. Regarding depth of sowing I consider 1in. deep enough. With regard to methods of cultivation, if it is intended to crop fresh burnt ground, the most payable method is to plough lightly or cultivate, drill, and harrow, or if the combine is used this work can be done before rain, because there would be no danger of weeds. This ground the following season should be loose enough to be drilled in and harrowed, and should grow a payable crop. The essential point is to have a loose mulch of fine soil on top and a firm seedbed below; with a deep, loose tilth the moisture dries out more rapidly. If sowing oats on stubble land, drill in early and most seasons the crop will grow ahead of weeds. Stubble ground to be sown with wheat is better left until the first rains have germinated; then this ground can be cultivated, drilled, and harrowed, or combined in and harrowed, and sown with heavier dressings of super and seed. Fallow ground, if well worked and kept clear of weeds, will do just as well sown dry as wet, because clean fallow usually shows no weeds after the first rain. After cultivation weeds will appear, so that if weeds have been kept under control while the ground has been lying fallow, there should be no reason why, if it is sown dry with, say, 60lbs. seed and 60lbs. or 70lbs. super, it should not grow as good a crop as if sown wet. If it be sown dry and makes an even start, then it has every chance of choking the weeds instead of the weeds gaining the upper hand."

Mr. D. Fitzgerald also read a paper:—"There are many points to be considered when dealing with the subject, 'Seeding,' and one of first importance is locality, because practices recommended for one particular district will not apply to others. So far as this district is concerned generally, the main factor is early sowing of the right variety of wheat, but the land to be cropped must be in the right condition to receive the seed, and there is certainly no better condition than well-worked fallow. Great care should be taken that the right class of land is fallowed; by this is meant patches of land that have a tendency to drift badly should be left in their natural state and ploughed up as raw land the following seeding. Land of a limestone rubble type can be fallowed almost any season without much danger of excessive drift, as would be the case with flats between rises. Rising land should be left well alone, especially if of a red, loamy nature. Good results can be obtained also from early sowing on clean land which is free from mustard and barley grass. The latter, I believe, is the biggest check to cereal crops. Land to be cropped showing signs of barley grass should be burnt and worked over with a light implement while still in a dry condition in order to cover the seed of the barley grass and other weeds, so that a good germination of these will result after the first rain. Approximately 10 days after rain this land should be worked over again with a shear plough, then harrowed and drilled with a disc or hoe drill, preferably in warm, drying weather, to kill any remaining grass which may not have been turned under. I do not favor the use of the combine because it plants the seed too deeply and does not give the best results as a weed killer. The ordinary drill will place the seed on a much more even bed than the combine. Variety of seed is a matter of personal opinion. I have tried many varieties, and during the past three years Nabawa (sown in April) has been outstanding. I do not advocate the sowing of this variety on land where weeds are likely to be prevalent because it is rather slow at getting away for the start. Of early varieties, the choice lies between Golden Drop and Canberra; not too large an acreage of the former should be sown, because it has a tendency to lodge badly. All necessary preparations should be made prior to seeding, implements looked over to see everything is in order, and any weak or worn parts replaced or procured to save delay should a breakage occur; such delays often mean the loss of bags of wheat at harvest time. Seed wheat should be graded and dry pickled prior to seeding so that no delay will result when conditions for cropping are ideal. I strongly advocate the use of dry pickle because none of the grain is injured, therefore a better germination will result, and there is not so much damage of wheat malting. It also enables the farmer to do the job at any time before seeding, because dry pickled wheat will not be affected whilst standing over a period of time. For the farmer who has no grader with a pickling attachment, the ordinary winnower with an open screen makes a very fair sample, and an effective duster for the dry pickling can be obtained at a reasonable figure and is quite suitable for the average farmer. Nothing should command more attention during the seeding months than the care of the working horses, for to put in the crop to time the horses must be kept in the pink of condition; they should be fed regularly and given time to eat their breakfast and dinner before going to the paddock; allow approximately 1¼ hours for each of these feeds. The night feed should consist of enough to last through the night in order that there will be a little chaff left in the manger the following morning. The horses' shoulders should be especially cared for and washed with cold water at the dinner hour, a process which takes only a few minutes for the largest team. Collars should be pounded each morning, and at least the shoulders of the horses should be groomed. Care should be taken to see the collars fit the horses' necks correctly, and I strongly urge the use of collar bags, providing they are used properly. The horses' feet should also be kept trimmed, and a good supply of water always available for the horses when they feel inclined to drink. Farmers should make a special study of their own particular farm and work same accordingly, because the same principle of working does not apply to all classes of soils.'' (Secretary, J. Dyke.)

TARAGORO.

May 5th.—Present: 11 members and five visitors.

Mr. J. Crooks read a paper on ''The Farm Flock.'':—''For the production of wool in this district I prefer the Merino, of good size, compact build, broad, with depth of side, well ribbed, clean faced from the eyes, with a dense fleece showing plenty of character and also a fair amount of yolk. The heavy, greasy fleece may not be so valuable per pound, but it makes up for loss in value by extra weight. The farm flock is usually handled in a more or less haphazard manner, and regarded as a side

line to bring in a few extra pounds during the year. In my opinion it should be treated as a branch of the general operations of the farm. More time could be spent in tending the flock, and the sheep should be frequently and carefully handled. Six weeks or two months before lambing all ewes should be crutched, so that at lambing time trouble from flies would be reduced to a minimum. When the sheep start to scour, they should be kept as clean as possible. A useful preventive is a good fluid sheep dip. It is also an effective cure for sheep that have been struck. Tar, kerosine, or oil have a detrimental effect on the wool, which results in consequently reduced prices. Lambs should drop from the middle of May to the middle of June. By this time green feed will have become established and provide nutriment for the ewe to produce a plentiful supply of milk. Do not overstock, sheep poorly nourished produce miserable lambs and a fleece of poor and light quality. A convenient-sized flock—according to what the holding can comfortably manage—will amply repay the farmer for the labor entailed. Rams should be changed about every two years, to maintain the standard of the flock. Before each shearing, the flock should be subjected to rigid culling, and any faulty sheep classed out. In this way a farmer should be able to keep his flock up to a fairly high standard.'' In the discussion that followed, Mr. E. James suggested drilling oats in for feed, and advised farmers to avoid overstocking. Mr. O. Guy said changing the flock from one paddock to another was advisable, and a small paddock near the homestead would assist at lambing time, so that the farmer could give full attention to the flock. Mr. M. Guy favored the Dorset-Horn crossed with a Merino ewe to produce lambs suitable for export. Mr. A. Edwards favored lambs dropped about the middle of April. Mr. J. Crooks, in reply, stated that rams should be young and not have more than 50 ewes to each ram. For export lambs, he favored the Southdown or Shropshire ram crossed with Merino ewes. Mr. H. Adams (District Instructor), who during the afternoon had visited several farms in the district, addressed the meeting on the subject, ''Soils and their Fertility,'' and gave suggestions on side lines suitable to the district. He also submitted a sample of ensilage, and mentioned many of its advantages on the farm for dairy cows. (Secretary, T. Winters, Cleve.)

June 16th.—Present: 10 members.

Our Local Bureau.—The Hon. Secretary, Mr. T. Winters, read the following paper:—''Having submitted our report for the past year's work as a Bureau, there are a few improvements that could be effected to retain, at least, if not to stimulate, interest of all members, and plainly it means this, that our Branch can only prove helpful to us as farmers if our interest in it is keen. Our Branch is only a small unit of a State-wide organisation, nevertheless we must keep our end up. An efficient secretary is necessary to any Branch. He it is who is responsible for records of meetings, &c., correspondence, arranging visits of Agricultural Instructors, and much else, and all done in an honorary capacity. I suggest, therefore, that by regular attendance, punctuality, and a live interest in the affairs of your Branch you can lessen his work and make it a pleasure. The choice of subjects to go on the syllabus from time to time can be considerably improved also. To-night is our Annual General Meeting; have the members come prepared with suggestions for the syllabus, and prepared to submit a paper? The choice of subject is better left to the writer responsible for the paper, as he will select a subject on which he is conversant. If members come prepared with suggestions, etc., for the drawing up of a syllabus the job is done more quickly and more satisfactorily. When you are responsible for a paper endeavor to submit it at its given time. Nothing destroys interest in the Branch more than failure to submit a paper when responsible for it. The other members come along to the meeting to enjoy and discuss the subject arranged, and members lose interest if no paper is tabled, especially when they have to return, say, from three to six miles. Farming provides us with many and varied subjects to suit all members, and preparing a syllabus should be an easy task. Let every member accept his share of the responsibility and offer at least one suggestion and undertake to write a paper. Our Branch has 18 members; we hold annually nine meetings; that fact if carried out would give us nine members to write on their selected subjects, and we have amongst our members farmers capable of doing so. Another fact which is rather easily forgotten by members, and one which the secretary loathes, is the payment of subscriptions and fines. Prompt attention to this fact should need no stressing from the Secretary and Treasurer. These are only a few suggestions given to assist our local Branch, and as Secretary, I trust that the coming year's session will enable us to derive in full the benefits of our local Bureau.'' (Secretary, T. Winters, Cleve.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

KALYAN.

February 22nd.—Present: Nine members.

Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Lessons Learned from the Past Season."

BLOWFLY STRIKE IN SHEEP AND THE "MULES" OPERATION FOR REDUCING THE INCIDENCE.—At a further meeting held on March 23rd, Mr. J. Wallis read the following paper:—"Mr. J. H. W. Mules, of Woodside, who owns a small but valuable flock of 'Peppin' Merino sheep, carried out some observations which led him to believe that the irritation of the skin by urine in the breech of the Merino ewe, was the chief predisposing factor to blowfly strike. He found that the most susceptible sheep have a fold of skin about ¾in. high, which extends from the sides of the root of the tail downwards and forwards on the belly, where it peters out. The folds encircle the vulva about 1in. from the middle line, and carry wool sufficiently close up to the inside edge to project inwards and touch the fold of the other side; the result was that the animal could not urinate without soiling the wool, which was practically wet continuously and matted together and rotted by bacterial action. As a result the skin beneath became eczematous, and at the root of the wool there was a collection of serous weeping from the skin and a collection of pus-like material with a putrid odor which was no doubt attractive to blowflies and would be an excellent breeding ground for young maggots. Mr. Mules' procedure is to anticipate the slower breeding methods by removing the folds by a surgical operation. He does it by pinching the fold in the jaws of a 'Burdizzo' castrating pincers, and while holding it there cutting away the projecting skin with a sharp knife. There is no bleeding; the sheep, even if full grown, makes very little fuss, the edges of the wound pressed together by the clamp remain adherent and in a few days the clamped edges slough away. As a result of the operation the ewe lambs grow up with a clean breech approaching in appearance that of the Leicesters. Mr. Mules' observations on grown ewes treated is that where they were previously susceptible to attack (sometimes many times in a season), after the operation they became to all intents and purposes immune. At the request of Dr. Lionel Bull, Chief Government Bacteriologist at the Adelaide Hospital, who visited Mr. Mules's homestead in company with Sir Charles Martin, Chief of the Department of Animal Nutrition of the C.S.I.R., Mr. Mules took observations to see how long it takes a sheep's skin to become susceptible to urine irritation. From when urine stains were first noticed to the strike was 21 days. By removing the skin on one side only Mr. Mules found that the sheep would be susceptible on the untreated side and immune on the treated side. Of course it is quite likely that in a sheep so struck the maggot infection would quickly spread to the treated side, this is only to be expected. It appears as if the practical man amongst sheep, following on the lines indicated, will be able to carry forward the blowfly investigation in a sweeping stride. If the operation reduces the incidence of the breech strike in ewes down to the percentage of the body and head strike the blowfly trouble in Australia would cease to be a major factor. The treatment of lambs during the tailing operation would certainly appear to be worth while. The development of an instrument which would pinch and sever the skin in the one operation would appear to be indicated, but in the meantime the 'Burdizzo' pincers (or masculators), already in the hands of a number of stockmen, will answer very well. What is now needed are some large scale experiments on established flocks. Mr. Mules' treatments date back from 1929.'' (Secretary, R. Lang.)

PARUNA.

June 10th.—Present: 13 members.

The evening was devoted to a Question Box. Each member had to ask a question and also answer one. Mr. C. Webb asked which was the best method of destroying rabbits? Mr. Hondow replied, and suggested a shortening of the time limit for each landholder to destroy the pest. In this district three months were allowed in which to do the work. Mr. Hondow said that if the time was cut down to, say, a fortnight, farmers would soon have rabbits under control. He explained the reason for adopting his plan, and said that if one man got to work early and made a thorough job of his farm and cleaned out all the rabbits, and a neighbor failed to get his done until late in the season, the rabbits on the latter farm would migrate on to his neighbor's farm and he would be just as bad off as ever. (Secretary, F. Sumner.)

SOUTH AND HILLS DISTRICT

CURRENCY CREEK.

May 23rd.—Present: 14 members.

Care of the Farm Team.—Mr. E. Fuller read the following paper:—''Every farmer should devote an hour or two every day to his team. Good, warm stables are necessary and they should be enclosed on three sides and open to the east, to avoid cold, westerly winds in winter. The stables should be cleaned out every day and dry straw put in for bedding. Horses should be groomed down every morning to remove dry sweat and dirt. Care should be taken to ensure working the horses in well-fitting collars. It is advisable not to pull the collars too tight; this has a tendency to draw the skin and cause irritation, and after a while a sore shoulder. Sore shoulders should be washed every night and ointment applied. Lard is a good dressing for sores; it keeps them soft and does not allow them to crack. If working horses over stumpy land, use back bands. The back band will reduce the friction considerably by taking jerks the shoulders would otherwise receive. During seeding it is important to get an early start in the mornings and not work too late at night. Horses should be taken out of the plough by sundown. One round after sundown takes more out of them than four or five in the mornings. It is not a good plan to have particular places in the team for certain horses; change them and give each horse the opportunity of proving itself on the rein. If the work is hard, add a few double handsful of oats to the chaff for the midday feed. Feed, water, and look after the team and they will well repay any trouble and care exercised on their behalf.'' In the discussion which followed, the Secretary asked what the writer put in water when washing horses' shoulders. Mr. Fuller used eucalyptus skin soap and found it excellent. Mr. Kemp used salt and water. Mr. Holme thought that when the team was working well each horse should be put in the same places. Mr. Skewes advised putting a chaff bag under the collar when a horse had sore shoulders. Mr. Burgan asked, ''How many times should a horse be watered whilst in work?'' *Answer*—Twice a day. Mr. Kemp wanted to know which was the best horse for farm work—heavy or light. The writer favored a medium draught. Mr. Holme asked, ''If feeding on oaten chaff should oats then be added to the chaff?'' *Answer*—Yes; at dinner time. (Secretary, D. Gordon.)

HARTLEY (Average annual rainfall, 15in. to 16in.).

April 20th.

Members visited the Murray Bridge Branch and took charge of the meeting held on April 20th. Excellent papers were contributed by Mr. C. Fahrmann, on ''Poultry on the Farm,'' and Mr. Hudd spoke on dairying.

THE PIG INDUSTRY.—At a further meeting on May 18th, the following paper was read by Mr. H. Brook:—Feeding is a very important aspect of pig management. Feed

The GENERAL MANAGER, Metropolitan Abattoirs Board,
Box 573E, G.P.O., Adelaide.

ALSO MANUFACTURED—

Blood Manure Bone Manure

is cheap and plentiful at present, which makes pigs a paying proposition. For sty feeding grain is necessary to supply protein. The best grains are crushed wheat, peas, or barley. Milk and house slops supply the liquid needed. Good convenient markets are available for the right type of pigs. The climate is temperate, so that very little shelter is required. Keep all places clean in order to keep down diseases. In this district pigs should be regarded as a side line to dairying and wheat growing. Grain and milk are plentiful, so that the pigs can be fed cheaply. Water is very necessary to good health, and should always be available. Build sties in such a way as to provide for good drainage. A straw roof is preferred; it is warm in winter and cool in summer. Water trough can be made of wood or cement, both of which are cheap and lasting. Self feeders are only used wh[illegible]ing is carried on. Sties measuring 8ft. x 16ft. will be quite large enough. Floors should be 1in. to 1½in. higher in the sty to allow for drainage. Cleanliness is essential. Keep the sties and troughs clean and have regular feeding times. Do not feed too much at one meal. The trough should be about 10in. at top and not too deep. The Berkshire is the most popular breed, and the young pigs fatten quickly. These have small litters, but are quiet natured. Yorkshires need plenty of shelter, because they are subject to sunscald. Tamworths are slow fatteners; better results are secured if crossed with the Berkshire. The Poland China is more suitable for the bacon breed. The Tamworth crossed with the Mid-York produces excellent bacon pigs. The Tamworth is a prolific breed, and the sows are good mothers. Milk is an excellent food for pigs, and is especially suited for sows and young pigs. The boar has a marked influence on the quality of the litter. The boar should be chosen from a large litter, and have a masculine appearance.'' Mr. R. Cross read a paper, ''Preserving Wood and Metals.'' (Secretary, D. Harvey.)

MOUNT COMPASS.

June 2nd.

Annual Meeting.—Over 150 members and friends attended the fourth annual meeting of the Branch. The President (Mr. Antony S. Kidman) presided. A party from Victor Harbor, under the leadership of Mr. G. Solley, supplied musical and elocutionary items. To stimulate interest in the Bureau amongst junior members, the Branch has organised horse and cow judging and potato growing competitions. These were won by Masters M. Williamson, S. Miller, and K. Peters. Mr. H. M. Hale, of the Adelaide Museum, gave an instructive address, illustrated with lantern slides, on ''Reptiles and Fishes.'' The Vice-President (Mr. H. B. Peters), on behalf of the Branch handed the President (Mr. Kidman) a set of serviette rings and candlesticks. Mr. Kidman has set an excellent example to members, for during the past four years, in spite of the fact that his home is in Adelaide (40 miles away) he has not missed more than three or four meetings. The average attendance of members during the past year has been 41 at each meeting. (Secretary, C. Verco.)

MYPONGA (Average annual rainfall, 28.94ins.).

May 19th.—Present: 14 members and nine visitors.

Wool Classing.—The Hon. Secretary (Mr. C. Martin) read the following paper:—''The main points in classing wool are to see that each class is evenly matched and prepared in an attractive manner to place before the buyer, who will then purchase at the highest possible price with confidence. Some buyers only buy the best of wools —those containing the lightest and brightest fleeces—and such a buyer will pass an unclassed clip. It sometimes happens that a buyer is compelled to purchase wool that he does not want, on account of the lot being badly classed, and in consequence he will only give a reduced price because he must allow for the possibility of loss in reselling the wool he does not require. More often speculators buy up unclassed lines of wool, reclass them, and nearly always sell at a good profit. Classing assists the buyer to correctly estimate the yield of wool. Classing means dividing the clip into lots as will best meet the requirements of different wool buyers and in such a way as to enable them to most correctly ascertain the yield of clean scoured wool. Before classing, the fleeces are carefully skirted, all bellies, faulty, dirty wool and locks and stains removed. Then the fleece is rolled neatly, leaving the shoulder wool on the outside, this usually being the best wool of the fleece. To skirt a fleece, start behind the shoulder, taking off any dirty, faulty, or burry wool; work towards the neck, then turn and work back towards the breech; the latter wool is usually much stronger than the rest of the fleece, and in districts where burr or grass seeds are prevalent this portion of the fleece will be most affected. All burry wool should be removed and made into pieces. The four main factors in classing wool are condition, color, quality, strength and length of staple. Condition denotes the yolk and earthy matter which the fleeces contain. Merinos are chiefly classed on condition. Quality is a very important point which has to be taken nsideration, and means the fineness or coarseness of the fibre. Different wools ifferent spinning qualities, and each quality is used for a different class of l. Merino is the finest wool; the spinning quality starts [illegible] 60's, and goes s, sometimes to 80's. Crossbreds range from about 40's to [illegible]'s, and Lincolns 36's to 40's. Counts of spinning quality indicate the number of hanks of 560 that can be spun from 1lb. of scoured wool. Colour is another important item to sidered, although color and condition very often go together. The brighest fleeces enerally the lightest in condition. An exceptionally heavy fleece, in most cases, is yellow, and is called dingy. Rams' wool is very often light in color, but usually avy in condition. On no account should rams' wool or black or grey fleeces be in other classes. Rams' wool is much harder to scour than other wools. A fleece ning an excess of yolk is yellowish in color, and [illegible] heavy, although it will y scour white. Tick stains on wool caused by the parasite of that name, if stained y, will not scour out white. Much depends on the throwing of the fleece on to the e. If this is done well, the wool-roller can do his work quickly and correctly, and most of the second cuts and locks drop out of the fleece. When classing crossbreds, ke as few lines as possible. Three classes will generally cover all requirements:— Fine; (2) coarse; and (3) dingy and discolored fleeces and those which do not ch in the other two lines."

SHOAL BAY.

May 17th.—Present: 10 members.

R. W. Chapman brought forward the subject of the "cricket" pest now being rienced, and stated that he found that they not only lived in cracked ground and he grass itself, but in a loamy river soil they were burrowing under the earth and the roots of plants.

E SHOULDERS.—Mr. M. Havelburg said that sheepskin, with about 1½in. length of cut to the shape of the collar and put inside the lining, was a good preventive re shoulders. (Secretary, E. Bell, Wisanger.)

CROWN LANDS.

LANDS TO BE OFFERED SHORTLY.

Lands to be offered in the Hundreds of BLACKER, BOOTHBY, BROOKER, BUCKLEBOO, BURGOYNE, CARALUE, CARAWA, CARINA, COLTON, COOTRA, CUNGENA, DUFFERIN, FINLAYSON, HASLAM, KIANA, KOONGAWA, LAKE WANGARY, McLACHLAN, MINBRIE, MINNIPA, MITCHELL, MOODY, MOORKITABIE, MORTLOCK, MOSELEY, PYGERY, ROBINSON, ROUNSEVELL, SHANNON, SMEATON, SOLOMON, ULYERRA, VERRAN, WANNAMANA, WRENFORDSLEY, and YADNARIE.

When offered, full particulars will be published in the *Government Gazette*, and plans and detail may be obtained on application to the Director of Lands, Adelaide.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January [illegible] July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available [illegible] conditions under which they may be applied for.

Copies [illegible] may be obtained on application to the Director of Lands, [illegible], Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

R. S. RICHARDS, Commissioner of Crown Lands.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, &c.

Eyre Peninsula (Eastern), at Kimba, Monday, October 3rd. (Secretary, Mr. M. J. H. Martin.)

Eyre Peninsula (Central), at Wudinna, Wednesday, October 5th. (Secretary, Mr. Duncan Duguid.)

Eyre Peninsula (Southern), at Cummins, Friday, October 7th. (Secretary, Mr. H. M. Roberts.)

Non-Irrigated Fruit Districts, at Tanunda—Lone Pine Branch, November 1st. (Secretary, Mr. T. Fromm, Tanunda.)

The opening session of each Conference will take place at 10.30 a.m. Papers, questions, &c., for Conferences should be forwarded to the General Secretary, Agricultural Bureau, about a fortnight before the dates mentioned above.

Christmas Gifts to the United Kingdom—Proposal of Australian Overseas Trade Publicity Committee.

The Minister for Commerce announces that the Australian Overseas Publicity Committee has framed proposals for the distribution in England and Scotland of Christmas parcels containing an assortment of Australian primary products. The parcels, in accordance with orders lodged in Australia, will be packed and despatched by the Committee's representatives in London.

In making available the details of the proposal, the Minister stated that the Trade Publicity Organisation was created some six years ago for the purpose of assisting the marketing of Australian products in Great Britain by means of advertisment and general publicity. The administration of the scheme was vested in a Committee in Australia which functioned in association with the Department of Commerce, and the executive work was carried out by a Director in London (Mr. A. E. Hyland).

The industries associated with the scheme were those of dried vine fruits (currants, sultanas, and lexias), dairying, canned fruits, fresh fruits (apples and pears), eggs, and honey, and the necessary finance was obtained by contributions from the industries concerned. The Commonwealth Government also contributed.

The Publicity Committee in deciding upon its Christmas Gifts scheme desired to provide an opportunity for the people of the Commonwealth to send to their relatives and friends in the United Kingdom a Christmas gift consisting of a variety of the choicest Australian products, and by doing so to bring these products more prominently before the buying public of the United Kingdom, thus securing an excellent means of advertisement.

The parcel will contain 2lbs. of sultanas, 2lbs. of currants, 1lb. of raisins, 2lbs. of butter, 1lb. of cheese, ½ dozen eggs, 1 tin of canned peaches, and 1 tin of canned pears. The total cost to the sender in Australia, including exchange and all delivery charges, will be 13s. 4d.

Orders for parcels may be lodged in all States, and in the case of the State of South Australia should be addressed to Mr. C. Harding Browne, Trustee Buildings, Grenfell Street, Adelaide. The orders should clearly indicate the names and addresses of both the sender and the recipient. Any further particulars may be obtained from the State representative referred to.

In the selection and purchase of the commodities required for the parcels, Mr. Hyland will have the assistance of officials of the Australian Marketing Boards and of the Commonwealth Government expert officers, and so there will be assured a freshly packed parcel of selected high quality articles.

The Minister said that he was confident that the people of Australia would welcome this opportunity of sending with very little trouble an excellent Christmas gift to their relatives and friends abroad. In addition to this personal aspect of the proposal, they would have the satisfaction of materially helping to bring about an expansion in the markets available for our products abroad—a very necessary requirement to the development of Australia's industry and trade.

The World's Wool.—Empire Marketing Board Survey.

The leading position of Australia among the producers of the World's Wool is clearly brought out in the Wool Survey which has just been issued by the Empire Marketing Board. The survey is a work of over 230 pages, published by H.M. Stationery Office, London, and priced at 2s. It estimates, country by country, the sheep population and wool crop of the world. Australia, with over 103,000,000 sheep is only equalled or surpassed by Russia. There are between 700,000,000 and 800,000,000 sheep in the world, a third of them in the British Empire. A census of the world production of wool shows Australia as the largest raw wool producer. Since 1924 Australia has provided a quarter of the world's wool, while the rest of the British Empire produces another quarter. The export trade and the trend of prices are next studied, and the survey also includes an account of the lesser animal fibres, mohair, cashmere, camel hair, alpaca, &c.

Prices.—The survey concludes that a large part of the price fall since the war has been due to the rise in the value of money, but adds that generally speaking wool prices have fluctuated more rapidly than the general commodity index. People economise on woollen garments and make them last longer. Demand is elastic, but the supply of wool is inelastic, so increased demand should show itself at once in the price. No large stocks have been allowed to accumulate through efforts to maintain prices.

Export Prospects.—Russian wool is almost entirely carpet wool, and the Russians import finer wools. The United States imports carpet wools. Neither of these great producing areas is likely to become an important exporter of wool in the near future.

Butterfat Output Competition.

Five years ago the United Dairy Cattle Breeders' Association of South Australia inaugurated an annual Butterfat Output Competition among those of its members whose herds were under official test, and during each year a gold medal has been presented to the owner of the winning herd.

The winners have been—

1927–28.	Mr. C. J. Morris, Monteith	556.58lbs. butterfat.
1928–29.	Mr. J. A. J. Pfitzner, Hampden	456.81lbs. butterfat.
1929–30.	Mr. C. J. Morris, Monteith	496.69lbs. butterfat.
1930–31.	Mr. C. J Morris, Monteith	465.21lbs. butterfat.
1931–32.	Mr. C. J. Morris, Monteith	560.94lbs. butterfat.

DECORATION

A summary of the fifth year's competition is set out hereunder, and the conditions under which the competition was held were as follows:—

1. No herd of less than six cows was eligible to compete.
2. In a herd of more than six cows, 25 per cent. of the number did not compete.
3. At least one cow in every six or part thereof had to be a matured animal—five years or over at time of calving.
4. The handicaps were—

For cows under two years at calving	80lbs. butterfat.
Two years but under three years at calving	60lbs. butterfat.
Three years but under four years at calving	40lbs. butterfat.
Four years but under five years at calving	20lbs. butterfat.
Five years and over at calving	Nil.

NOTE.—Messrs. J. H. Dawkins, W. S. McAuliffe, and the Dunleith Pastoral Company submitted more than six cows to official test, but did not have sufficient matured cows for eligibility.

Publications Received.

Royal Agricultural College Students' Magazine, Cirencester, Vol. XIX., Part I. In an accompanying letter the editor mentions that owing to the war the college closed down for a number of years and lost touch with numbers of its old students, from whom their *Alma Mater* would like to receive some news.

NO BREAKDOWNS

during harvesting, because

Mobiloil

stands up

YOU can't afford any risk of tractor breakdown during harvesting. That is one reason why you should use Mobiloil. You want to get your harvesting done as quickly as possible—that's another. Still another reason is the need for the greatest economy. Mobiloil will give you that.

Mobiloil is made to stand up to the hardest work, and it will enable your tractor to stand up to it, too.

AGRICULTURAL INQUIRIES.

[*Replies supplied by Mr. W. J. Spafford, Deputy Director of Agriculture.*]

Soursobs in Cereal Crops.

Wasleys Agricultural Bureau: Is oxalic acid in soursobs detrimental to the growth of cereal crops? Reply—Soursobs when present retard the growth of cereal crops because of the fact that they use mineral plant food and moisture required by the crops, but the oxalic acid manufactured by the soursobs during their growth would immediately be changed on the death of the plants (*a*) by the decomposition of the organic matter, and (*b*) by combination with mineral constituents of the soil. If soursobs were grown in a soil for such a length of time that the acid produced led to the soil becoming sour, then the growth of cereal crops would be affected injuriously, but it is difficult to imagine how long it would take for this to happen in the soils in which soursobs flourish, because most of them are well supplied with lime to counteract excessive acidity.

Stage at which to Cut Hay.

Blackheath Agricultural Bureau: At what stage should one cut wheaten or oaten hay for feeding to milking cows chaffed, to produce the maximum return of milk? Reply—In districts where the climatic conditions are such that cereal hay can be properly cured in late September or early October, wheat and oats grown for hay for cows should be cut soon after flowering and before the grains show much sign of development. Such hay has higher digestibility than that made from more mature crops, and is of a laxative nature, which also helps cows in milk. With such early-cut hay, more care is necessary in curing, because cool weather is sometimes experienced while it is in the stook, and there is then considerable liability of the development of moulds, and the blackening of some of the hay.

Storage of Oats.

Miltalie Agricultural Bureau: "Is it necessary to provide ventilation in an over-ground concrete silo in which oats are to be stored; if so, what method should be used?"

Reply—Success with storing grain in silos depends on drying the grain before shooting it into the receptacle, and then keeping *all air* away from the grain. No ventilation of any kind must be permitted, and, as a matter of fact, all masonry silos should be coated with whitewash, tar, pitch, bitumen, or some such substance before they are filled, to make certain that the receptacle is made airtight. Silos made of materials other than masonry should have any joints in the material coated with something that will make certain that no air gains admittance.

"Would a concrete floor in silo be all right for storing oats for a period of, say, four years, or would a wooden floor be necessary?"

Reply—Concrete floors in silos are quite suitable for storing grain for years provided that moisture is not rising through the floor.

Mangels.

Rendelsham Agricultural Bureau: "What is the best month to sow mangel seed?"

Reply—Mangels are summer-growing plants, and so the seed is sown in the spring. In seasons when the soil has warmed up in September the seed can be sown in that month, but when the cold weather continues into the spring it is better to wait until October. The so-called mangel seed is really a mass of corky material containing from three to five seeds. Usually, and particularly if the seed was soaked before sowing, all of the seeds in the capsules germinate, but on other occasions some of them germinate a long while before the remainder. It is essential to carefully thin out mangels before the young plants get too large, one of the main reasons being that the plants arising from a single capsule often twist themselves around one another and so lead to misshapen roots if left to mature.

Ford 30-cwt. Stakeside Truck (131½" wheelbase) with enclosed cab and special malleable steel wheels—dual at rear.

- New 4-speed Gear Box
- New Stronger Front Cross Member
- New Heavier Front Spring

STRONGER and MORE POWERFUL is this improved 30-cwt. Ford Truck . . . .

RUGGED strength and an unusual capacity for heavy work have always been characteristics of the Ford 30-cwt. Truck. Yet both strength and performance have now been notably improved.

Performance . . . The New 4-speed Gear Box (with Power Take-off) gives higher road speeds and tremendous pulling power for soft ground or excavations . . . 5 ball and roller bearings reduce friction . . . In all forward speeds, the entire drive (from engine to wheels) is on ball or roller bearings . . . A Power Take-off is provided for tipping or for belt-work operations.

Strength . . . The stronger Front Cross Member and heavier new 2½" Front Spring provide a greatly strengthened front suspension, capable of withstanding hard driving at speed with capacity loads over roughest tracks. Radiator, engine, clutch and transmission are relieved from all road strains.

Strawberry Clover.

Brentwood Agricultural Bureau: "Is it possible to establish Strawberry Clover on the salty swamps in the district?"

Reply—Strawberry Clover will grow in fairly saline conditions, but in all probability most of the swamps near Brentwood are much too salty for this fodder plant. In those places, however, where the edible rush-like plant has appeared it would be well worth trying Strawberry Clover, and perhaps the best way to make the trial would be purchase a small quantity of seed. Scarify the seed by spreading it in a thin layer on a table or bench, and gently rub it with a board to which has been tacked or glued a sheet of sandpaper. Sow the seed in a plot that can be easily watered. Keep the plot well watered during spring, so that the plants make a dense mat of growth. Cut the plot of clover into small sods about 1in. to 1½ins. square with a sharp spade, and throw these sods into the mud of the swamp, trying to space them about 2ft. to 3ft. apart each way.

HORTICULTURAL INQUIRIES.

Dead Limbs in Apricot Trees.

At the Conference of Southern Branches of the Agricultural Bureau the following questions were included on the Agenda and replies supplied by Mr. C. H. Beaumont, District Horticultural Instructor:—

"What is the cause of apricot trees dying in the Strathalbyn district and the remedy for same?"

Reply—There are several causes for this trouble, but the main reason in the Strathalbyn district is the shallow soil and tight red clay subsoil. The trees will not live to any great age in such a soil. Another reason may be a want of water or too much water, both having a similar effect. Further, the trouble may be the result of very heavy pruning; this causes a gumming, and it is probable that a bacterial action may cause limbs to die.

Borers Attacking Fruit Trees.

"What is the correct time to spray prune trees to prevent borers attacking the fruit?"

Reply—Spray as soon as the caterpillars are noticed; this, however, may not be at the same time every year.

Crown Gall.

"Cause and treatment of the swelling cancer on the main stems of almond trees?"

Reply—The swelling is caused by "Crown Gall," or "Plant Cancer." There is no cure for it in the later stages, but it may be stopped if observed on trees up to 3 or 4 years old by cutting out the cancer with a sharp chisel and painting the wound with white lead. Other trees are affected in the following order:—Peaches, plums, pears, and it is seen occasionally on the apple and vine. It is considered to be mainly a nursery trouble, and the trees are affected before planting out. It is always worse in sandy soils.

Pruning.

"What will be the effect on matured fruit trees if the leaders are not pruned?"

Reply—There would be no special effect except that the spindly growth would be broken off by the wind and thus perhaps seriously damage the tree.

Cincturing.

Speaking of his observations in the vineyards in the Langhorne's Creek district, Mr. C. H. Beaumont, in a short address at the Southern Conference, said he was surprised to see the damage done to vines, especially Zante currants by twisting the young vines on

the trellis vines and failing to remove them; the vine was thus practically cut into sections by the constriction caused by the wires, and some thousands of vines had died in the past dry seasons. This may have been caused to some extent by careless cincturing. Some growers made a deep cut into the main stem and then wondered at the weak condition of the vine. The cut is needed *through the bark only,* and the bark is very thin. It is advisable to get the vines off the wires and tie them in place, taking care when cincturing, or the whole vineyard will die out.

VETERINARY INQUIRIES.

[*Replies supplied by Veterinary Officers, Stock and Brands Department.*]

Lameroo reports stallion in good condition, but lacking in vitality. Reply—Do not use stallion for service for a couple of weeks. During this period give one teaspoonful of powdered nux vomica night and morning for seven days. To give, mix with treacle and smear on tongue. Give four feeds daily of oaten chaff and bran and crushed oats. Do not over-feed. See that horse gets plenty of exercise each day and regular green feed. When using again limit service to one per day.

Paruna asks must a sheep earmark be registered? Reply—Sheep earmarks are not registered, the owner of a registered sheep brand being permitted to use any earmark he desires provided that pliers are used and the mark does not exceed the regulation size of ¾in. x ½in., except in the case of a slit, which may be 1¼in. from the tip of the ear. It is contemplated introducing a Bill to provide for the registration of sheep earmarks.

Point McLeay asks for symptoms of pneumonia in cattle. Reply—The symptoms of all acute types of pneumonia (including pleuro-pneumonia) are:—Rapid breathing (the breathing is done mainly with the abdominal muscles), high temperature (105° to 107°), disinclination to move, head is poked out, appetite is lost or is poor, rapid falling off in milk supply, and an important symptom is the presence of a cough.

Naracoorte reports death of calves nine months old. Frothy discharge at back passage, practically unable to stand. Reply—The condition is digestive in origin and caused through improper feeding. It is suggested that the calves be put in a fresh paddock and that any that are not doing well be put on to whole milk for a week and then gradually put on to skim milk. The calves should be fed three times daily and should not receive too much at each feed. Change over to a good calf food (linseed meal) for a time. Keep utensils clean. If any calves are scouring, isolate, give a dose of castor oil, and put on to whole milk.

6, *Park Terrace, Parkside, asks information re registration of stallion.* Reply—It is not necessary for the draught stallion to be registered in a stud book. The fee for examination is one guinea per horse, plus cost of transport. No charge is made if the stallion is examined at annual stallion sale or Royal Agricultural Show.

Wolseley has mare nine years old, big eater, but is losing condition. Reply—(1) Starve for 18 hours. (2) At end of that time give following drench:—Raw linseed oil, 1½ pints; oil of turpentine, 4 tablespoonsful. (3) Subsequently give one tablespoonful of Fowler's solution of arsenic night and morning for a fortnight. To give mix in a small damped feed. (4) Feed four times daily on good quality chaff, bran, and crushed oats. (5) Have horse's teeth attended to if necessary.

Brentwood reports (1) *horses six and eight years with swollen gums;* (2) *Horse with sore in top of lip.* Replies—(1) Give affected horses the following drench:—Raw linseed oil, 1½ pints; oil of turpentine, 4 tablespoonsful. Have chaff damped. If molar teeth are irregular they should be filed. (2) The only effective treatment is to open up the sore with a clean sharp knife, search for any foreign body, and syringe wound out with lysol solution.

Use TOP BRAND Supers, remembering

Australia can only be saved financially by the development of NEW CAPITAL.

Farmers can, by MAXIMUM PRODUCTION, lead the way in the Development of Capital.

MAXIMUM PRODUCTION is only possible from WELL-FED SOILS.

Cutting FERTILIZER DRESSINGS is false economy, and leads to disaster.

It is better to seed, and thoroughly fertilise one-third of your tillable land, and let two-thirds lie idle, than work it all and wear out machinery, only to harvest half a crop.

ALSO MANUFACTURED—

Blood Manure **Bone Manure**

Coomandook, two pigs, four months old, suddenly lost use of legs. Reply—The condition is paralysis. Put sows in warm, dry well bedded down shed. Feed on whole fresh milk and a little meat (rabbits, &c.), no grain. See that sows get plenty of green feed (grazing). Put a supply of wood ashes out for them.

Mount Gambier reports that all sheep on his property that at any time get their skin broken develop tetanus. Reply—Be very careful at "marking" and "shearing" time. Temporary yards should be used for marking, and I would suggest that you try the Burdizzo pincers for both castration and tailing. All old sheep yards should be cleaned out, and litter, old manure, &c., burnt. The making of new yards should be considered. Anti-tetanic serum is very effective both as a prophylactic and a curative. For curative purposes, however, the cost is high. As a preventive for a sheep, 100 units (U.S.A.) should be injected subcutaneously as soon after the wound is received as is possible. As a curative for a sheep, 2,000 to 3,000 units should be injected subcutaneously. The later doses depend on course of the disease. Price:—One phial containing 500 units (U.S.A.) costs 1s. 6d. The serum can be obtained direct from the Chief Quarantine Officer (General), Peel Chambers, Peel Street, Adelaide. A hypodermic syringe and needles would be required. Should you require any further information get in touch with Mr. Curtis, Stock Inspector, Mount Gambier.

Macclesfield asks (1) *should a cow be dried off before calving, and* (2) *treatment for horse with itchy fetlock.* Replies—(1) It is advisable especially in case of a heavy milker. Do so six to eight weeks before calving. The cow can be served when she comes on heat (21 to 28 days after parturition). (2) Clip hair off fetlocks. Rub in following mixture daily with a brush:—Paraffin oil, 1 pint; solution of hard soap, 1 gallon. (Add paraffin oil to soap solution whilst hot. Keep mixture stirred whilst applying.)

Langhorne's Creek has horses troubled with lice. Reply—Treatment:—(1) Groom daily. (2) Feed well. (3) Apply one of the following dressings:—(*a*) paraffin oil, 1oz.; linseed oil, 19ozs.; (*b*) non-poisonous sheep dip (at strength recommended for dipping). Whatever dressing is used must be persisted in and repeated for several weeks in order to destroy fresh lice as they hatch out. The eggs are resistant to dressing. (4) Clean out stables thoroughly.

Bordertown reports mare stands with legs widely apart and rubs itself on the belly on rails. Reply—1. Try the following treatment:—(1) Starve for 18 hours. (2) At the end of that time give following drench:—Raw linseed oil, 1½ pints; oil of turpentine, 4 tablespoons; shake thoroughly before giving. (3) Subsequently give one tablespoonful of Fowler's solution of arsenic in a small damped feed night and morning for a fortnight.

Langhorne's Creek reports pigs with back passage protruding. Reply—The condition is due to some bowel irritation. See that the young pigs get plenty of exercise and grazing. Cut down supply of grain (barley). A good supply of wood charcoal should be made available to them. If condition continues report occurrence to us.

Ceduna asks for method to rear a foal by hand. Reply—The foal can be raised on cow's milk. Get milk from fresh cow and preferably one with milk of a low fat content. To prepare milk proceed as follows:—Dissolve one tablespoonful of sugar in a little warm water. Add three to five tablespoonsful of lime water, then enough milk to make a pint. Feed ¼ pint every hour for the first few days, always warming to blood heat. Use an ordinary baby's bottle and strong nipple. Wash after each feed. As foal grows increase amount of milk gradually (after a few days give six feeds and later only four). After three weeks discontinue sugar, but still add lime water. In five to six weeks sweet skim milk may be *gradually* substituted for whole milk, and after three months give foal all it will drink three times daily. At earliest possible age give foal solid food, *e.g.*, crushed oats, bran, and a little linseed meal. If scouring occurs give two to four tablespoonsful of equal parts of castor oil and olive oil. Cut out feed for three or four feeds.

THE MANUFACTURE AND UTILISATION OF SILAGE.

[By W. J. Spafford, Deputy Director of Agriculture.]

The storage of luscious green forage so that it retains its succulence, palatability, and digestibility is one of the recognised methods of preserving foodstuffs for farm livestock, and when saved in this form the fodder is known as Silage or Ensilage. It is by no means a new art to manufacture Silage successfully; in fact, it is very old, but was revived towards the end of the last century, and was then boomed, and made very rapid strides, mainly because the United States of America took it up seriously, after the appearance in that country in 1879 of the translation of a work on the subject written by M. Auguste Goffart in 1873, and of the "Book of Ensilage," by Dr. J. M. Bailey, of Boston, in 1880. Its manufacture made such rapid progress that in a very short time after the publication of the above works a conference of several hundreds of farmers was held in New York to compare their experiences of the fodder. That it is only the revival of an old art there is no doubt, because the ancient Romans left references to the storing of green fodder in underground chambers, and the Mexicans have for centuries stored, and are still storing, fodder in this way.

The credit for being the first man in Australia to store fodder as Silage is usually given to the late Mr. Charles Rake, of Enfield, South Australia, who not only manufactured it, but did his best to encourage others to make and use it. Despite this very early experience of Silage, and the fact that the comparative dryness of our climate favors such a foodstuff, it is only now becoming popular in this State, and although its value is now a little better known, much still remains to be done in this direction. It seems certain that if we are to make much progress with dairying, forage must be stored as Silage on practically all farms carrying milking cows. In many parts of the State we can produce with certainty very heavy growths of fodder plants, cereals, peas, and other leguminous crops in the Spring time, but they all quickly mature when the Summer season arrives, and from then until the Winter is over farm livestock are compelled to secure most of their sustenance as "dry" feed. The only green forage obtainable during this period is from the very limited area of irrigated fields, and from light grazings when the Summer rains have been exceptionally good, or when the Autumn rains are early enough to start the feed whilst the soil is still warm. The storage of some of the surplus forage in a succulent form for use during the period of "dry" feed keeps up the production of the dairy herd, and has the added advantage that the greater yield of milk is received during the time of normal shortage, when prices are at their highest.

The definition of the term "Silage" at the present day is the article obtained by storing green succulent forage so that it retains its succulence and much of its green color; and the word "silo" stands for the air-tight receptacle used for storing this succulent fodder.

Ensiling a fodder, or making Silage, consists in preserving green, succulent plants, so that they will remain green, or semi-green, and keep their succulence for a considerable time. Briefly, it is done by cutting the plant growth to be made into Silage when very green, and nutritious, and storing it under pressure, usually in air-tight receptacles of some kind, but sometimes in open stacks. Originally, Silage was always made in underground pits, the earliest ones being no more than holes in the ground; but later on these were improved by using masonry bottoms and sides. These underground chambers were followed by overhead receptacles, made of various materials, and these again by stacks made in the open air. In most cases considerable weight is applied. The resulting forage is of the same nature, whatever the system of manufacture, the difference between the various methods having to do mainly with the ease of handling the green stuff or the finished article, and with the amount of waste in preparation.

ADVANTAGES OF STORING FORAGE AS SILAGE.

When fed to dairy cows and ewes with lambs, good Silage has almost exactly the same nutritive value, pound for pound of dry matter supplied, as has green forage, and, as well as possessing equality with the best milk-producing foodstuffs, it has advantages over most other stored fodders. The palatability of practically all forage plants is increased by converting them into Silage, and so great is this palatability that animals which have been fed with the fodder will leave all other foodstuffs when good Silage is placed before them. The digestibility of most fodders is increased when they are stored as Silage in a proper manner, but its great advantage in this direction is that the digestibility of other foodstuffs fed in conjunction with it is also improved. This is particularly noticeable when Silage is given to animals grazing at the end of Summer and in the Autumn, on feed allowed to dry in the fields, or when they are only receiving hay as well as the Silage. Some of the forage plants not readily eaten by livestock because of the presence of spines, or tough fibres, and some of the rougher kinds, which will not cure into good hay, can be converted into Silage of fair quality, which will be readily eaten by the animals, and lead to a full milk flow.

Another great advantage of storing feed as Silage is that the job can be undertaken as soon as the crop is ready, without the need of waiting for fine weather. Provided really heavy rain is not falling at the time, the crops can be cut and carted to where the Silage is to be made, in any weather, and in those cases, when the crop is a little over-mature, some rain helps towards the production of first-class Silage. No matter how the Silage is made, no damage is done to it by birds or mice, and there is no danger from fire.

CHANGES OCCURRING IN THE MANUFACTURE OF SILAGE.

Considerable alterations occur in the forage between the cutting of the crop and its preservation as Silage, and the distinctive odor, peculiar flavor, increased palatability, softening of naturally tough fibres or spines, and the general attractiveness of the fodder are wholly due to these changes. As the changes are all-important in the manufacturing and also in the keeping of the fodder in a succulent form, some knowledge of them is necessary. The transformations that take place in forage stored as Silage are of both a chemical and a physical nature, but whilst the chemical changes are great and of much importance, the physical ones are only of minor account. Under all methods of making and storing this class of fodder, the alterations that occur are the same, but the degree of change varies with the method of manufacture adopted.

CHEMICAL CHANGES.

When green succulent growth is thrown together in a heap there is a rapid rise in temperature, and this increase of heat is brought about in the first place by the respiration of the live cells, and is continued after the death of the cells by fermentation and bacterial activities. The great bulk of the cells of green plants remain alive for some time after the plants are cut, and when thrown together in the heap these cells continue to breathe in oxygen and give off carbonic acid gas, and, as is the case with all other forms of life, in this process heat is evolved. These cells continue so to breathe while there is free oxygen present, and as soon as they have used all of this free oxygen, if the heat evolved is not sufficient to kill the cells, they begin extracting oxygen from their own materials, and this effort, combined with the rise in temperature, causes the death of the cells. The rise in temperature and death of the plant cells is a very rapid process, for there are millions of living cells thrown together in the mass, all breathing oxygen from a limited supply; and as the loss of heat from the mass is very slight, it is stored up, and the temperature quickly rises to the point necessary to kill the cells. It is not until after the plant cells are killed that the action of ferments and bacteria comes into really active play, but if sufficient free oxygen is present it will lead to so complete a decomposition of the material in the heap that it will soon be indistinguishable from well-rotted farmyard manure.

It is recognised that plants as they grow have the ferments and bacteria that will lead to their decomposition when suitable conditions offer, literally all over them. It is also known that the temperature surrounding these plants has only to be raised sufficiently high to kill all the plant cells, and the ferments and bacteria adhering to the outsides of the plants. Further, in all fermentative activities, each particular form of life attacks special portions of the organic matter, and produces as a result of its action a substance peculiar to its own kind. One of the commonest instances of this is the action of yeast, which attacks sugar in solutions, splitting it up and leaving alcohol behind. Now the product set free by each special kind of ferment or bacteria accumulates until in the end there is sufficient of it to act as a poison to the life that produced it, either killing or at least checking its activities. This is commonly seen with our friend the yeast in the making of sweet wines; here enough sugar is provided in the first place, so that the ferment produces sufficient alcohol to check its own activities, and the finished article has sugar left in it, although the yeast was not killed by artificial means.

It is having a knowledge of these above-mentioned natural activities and an understanding how to control them that enables the successful manufacture of good Silage with certainty, and the making of the particular type desired. When the temperature is allowed to rise rapidly to a point where the ferments and bacteria are rendered inactive before they have led to much splitting up of organic matter, with its resulting liberation of acids, what is known as "sweet" Silage is made. On the other hand, when the temperature is not allowed to rise high enough to kill the ferments and bacteria brought in with the green fodder, they continue their activities until the acids liberated by them have accumulated in sufficient quantities to stop their work, and then so-called "sour" Silage is the result.

It has been found (*) that practically all the free oxygen in the air surrounding the material being converted into Silage is used up in 4 or 5 hours, and the usual fermentation products—ethyl alcohol, acetic acid, and lactic acid—are present in appreciable quantities in from 24 to 48 hours after putting the forage together. As the activities of the plant cells weaken, moulds, yeasts, and bacteria become more animated; the moulds probably functioning for a few hours only; the yeasts disappearing in a few days; and the bacteria persisting for a good time longer. During these actions the temperature rises for about 15 days, and although decreasing after this time, remains fairly high for some months.

PHYSICAL CHANGES.

In the course of manufacturing Silage from green forage the color and general appearance of the plants undergo fairly considerable change, but in most other directions the physical changes are of little importance. Most Silage is of a brownish color, and this is practically always so when the temperature has been allowed to rise fairly high, when rather over-mature fodder is used, and when eight or more days are occupied in filling the silo or erecting the stack. When very sappy plants are put together quickly, and the Silage is heavily weighted down within a week of starting the silo or stack, the resulting material usually retains much of its natural green color. The weight of material, as well as the weights put on the top, squeezes the forage together and alters the general appearance of the plants by flattening them out. The ensiling process develops a peculiar but not unpleasant odor with nearly all fodders so preserved, but with some very sappy plants, or where the Silage is carelessly made, the odor formed can be extremely unpleasant to human beings. The peculiar odor of Silage, even when it has become rather strong and unpleasant, has no deterrent effect upon livestock, and as a matter of fact appears to be attractive to them. The taste of the forage is considerably altered in manufacture, varying, according to the method practised when making the Silage, from sharply acid to a sweetish-nutty flavor, but all forms are readily consumed by farm animals once they have tasted the Silage. The tissues of many plants are softened in the silo, and this is particularly noticeable with the spines of such plants as thistles of various kinds, which are thus converted into good forage. The fibre of most plants is rendered more digestible by the softening process referred to.

LOSSES IN MANUFACTURING SILAGE.

When it is remembered that the cells of the plants go on living for some little time after being cut, and that on their death ferments and bacteria lead to a partial decomposition of the organic matter, it is easy to realise that even in a first class silo which is practically air-tight, there is some loss of material through these activities. This loss is intensified in all badly constructed silos, and wherever portion of the material is exposed to the air, as when the top of the Silage in a receptacle is left uncovered, and on all sides and the top of stacks of Silage. The losses due to the last efforts of the plant cells and to fermentation are unavoidable, but the losses due to exposure to air can be considerably reduced, except in the case of stacks. That these unavoidable losses are fairly considerable is shown in the following table, the results there set out having been secured at the Missouri Agricultural Experiment Station in experimental silos built for the purpose:—

TABLE I.—*Unavoidable Losses in Making Silage.**

MAKING SILAGE.

As has been already pointed out, when it is desired to preserve succulent fodder so that it remains in a succulent condition, the temperature to which the mass of green stuff rises must be controlled—

1. So that the bulk of the bacteria are killed along with the cells of the plants; or

2. So that the cells and most of the bacteria, except the lactic acid forming ones, are killed.

In the first case the temperature is allowed to get fairly high before being checked, and in the other the check is applied before the temperature gets high enough to kill all of the useful bacteria. It must be remembered that it is only necessary to put green succulent growth in a heap, and the temperature will rise, due to the combustion that takes place by the activities of the living cells and the bacteria; and the slower this mass is put together the greater will be the rise in temperature. This is only reasonable, because both the cells and bacteria are very active when the supply of oxygen is large, and when the green stuff is put together quickly the weight on the mass is rapidly increased, so compacting it that the air is squeezed out, with the resulting check on the oxygen-loving life. Briefly, then, in the making of Silage a mass of green forage is put together, and then weighted down to compact it together, to squeeze out the air, and to prevent any more air entering it.

There are various methods of making Silage, but it does not matter much which one is followed, provided that a few simple rules are observed, and general care is shown. There are some variations in procedure depending upon the type of crop being ensiled, but most crops are handled in a very similar manner.

WHEN TO CUT THE CROP BEING ENSILED.

The green forage to be preserved as Silage should be cut while it is still really succulent and is well supplied with live and active cells, and to ensure a good "cure" the cut material should be put in the silo or stack whilst fresh and unwilted. The only exceptions to this cutting in an early stage of maturity and rapid transference to the silo occur when dealing with excessively succulent and watery plants, such as rape, kale, cabbages, &c., which preserve much better if allowed to become more mature, and if some of the moisture is allowed to dry out of them.

Of the crops usually converted into Silage the cereals wheat, oats, barley, and rye are in the best stage for cutting from a week to a fortnight after the heads appear, and in this stage, no matter how luxuriant the growth, they usually contain the correct percentage of moisture to make good Silage. The cereals can be converted into Silage of good quality if cut before the heads appear, but more weight per acre is obtained by waiting, as the cereals continue to increase in weight until about three or four weeks after full bloom, although from then onwards a continuous loss takes place until maturity is reached. The leguminous crops—peas and beans—should be cut when the bottom leaves are commencing to go yellow, and when the seeds are about full size, but still soft. Lucerne, clovers, and similar plants should have passed the period of full bloom before being cut, as they are liable to be too succulent if cut sooner. Maize, sorghum, and Sudan grass are usually allowed to stand until the bottom leaves begin drying before cutting for Silage; and in the case of maize, the grains should still be doughy although their skins are glazed. Sunflowers should be showing color in most of the flower-heads before cutting. Grasses should be well out in head if the best Silage is to be made from them.

Immature growth of most crops tends to make Silage which is soft and mushy, and it is usually necessary to wilt it to some extent before carting, or to mix it with over-dry material of some kind. Over-mature crops are usually much too dry to make good Silage, and if to be used should be moistened with water whilst being put in the silo or stack, and more weight should be used than for material cut at the right stage.

FILLING THE SILO.

In all cases, except when over-succulent plants are being ensiled, the forage should be put into the silo whilst still fresh, and many makers of Silage go so far as to declare that it should not lie on the ground to wilt to the slightest extent, and on no account should cut material be allowed to lie overnight. Rain falling during Silage-making does no damage to the materials, and only causes the inconvenience natural to carrying out such a type of work in the rain.

Different types of Silage are made according as the forage is thrown together quickly or the receptacle is filled more slowly, and although the resulting material is of good feeding value whether made quickly or not, most makers favor the slower method. It is found that a nutty-flavored Silage with pleasant aroma, which will keep almost indefinitely, is manufactured when a given quantity of forage is put in the silo each day for a period of six to 12 days, and the weights are applied as soon as the filling is completed. A minimum of 3ft. and a maximum of 8ft. of material should be put into the silo each day, and if for any reason more than a couple of days are to elapse before more material can be added, weights of some kind should be placed on the Silage, and remain there until the work of filling can be continued. Some makers follow the practice of filling the silo in three or four stages, by about one-third filling the silo, leaving it for a couple of days, repeating the quantity and again allowing it to settle, completing the filling in the fourth stage, and then weighting it down. Extremely good Silage is made in this way, but it is not of such uniform quality throughout the mass as when a regular quantity of forage is added daily to the silo.

When the silo is filled quickly and the weights added soon, so much air is excluded from the lower parts that slow fermentation results, and although the forage retains its green color much better than if the receptacle is filled slowly, the attractiveness and general quality is not quite so good.

It is usually recommended to thoroughly trample the outside edges whilst the silo is being filled, but when the forage being converted into Silage is sufficiently succulent, when weights are to be applied, and particularly when the material is chaffed before being put into the silo, this practice can be dispensed with.

The lime-washing or tarring the inside of masonry silos before filling tends to make the walls more air-tight and to protect them from attack by the acids in the Silage.

Some care must be experienced in entering partly-filled silos before re-commencing filling in the morning because of the danger from poisonous gases, and some agitation of the stagnant air is often necessary, such as would happen by feeding forage into it, or if a blower is used, giving it a run for a short while.

If the forage is chaffed before being put into overhead silos, elevators or blowers can be used to convey it from the cutter to the silo. The blower is the most efficient method to deliver chaffed forage, but a great deal more power is required to drive it than if an elevator is used.

When filling a trench silo the conveyances bringing the forage should run into the silo on top of the material to help press it together. When the silo is about half-full it is an advantage to further consolidate the Silage, and it can be done by driving horses backwards and forwards over the forage. It is very important with this type of silo to see that the Silage does not shrink to such an extent, after it is covered, as to leave a hollow below ground-level as a basin to hold water. Because of this it is usual to take about a fortnight to complete the filling, so that it is well consolidated, and then on the last day of carting, the forage is mounded up to about 4ft. above ground level, and allowed three or four days to settle before the earth is thrown on top of it.

CHAFFED OR WHOLE MATERIAL FOR SILAGE.

Silage of the very best quality can be made whether the forage is chaffed or stored whole. Chaffing the material facilitates the filling and emptying of overhead silos, and is suited to some of the coarser forages, such as Maize, Sorghum, Sunflowers, &c., whereas whole material is essential for stacks, and is generally availed of for earth pits and trenches.

If to be chaffed, the forage is cut into lengths of about ½in. to ¾in., and is delivered to the silo by a blower or elevator. Coarse forages are chaffed by a Silage cutter, a machine with the blades fixed horizontally on a roller, and made specially for the purpose, whilst finer-textured plants can be cut with the ordinary cereal chaff-cutter. The chaffed material should be delivered over the centre of the silo to prevent the settling of the heavy sections on one side, and more even distribution is brought about if a bag shoot is used to carry the material well down the silo. Regular distribution of the material when filling the silo leads to a more even settling of the Silage, and so better quality throughout the mass. Because chaffed forage compacts together better than whole material, less weight is required than for long stuff.

When whole material is being put into a silo or stack some difficulty is experienced in distributing it evenly, but if Silage of regular quality throughout is to be produced, it is essential that every effort be made to spread the forage evenly. When the crop has been cut with a binder, the sheaves can be placed in silo or stack without cutting the strings, and provided more weight is used on the mass just as good a quality of Silage will be made as from loose material. The strings will remain sound for some years if the crop was not too succulent when cut, and while they remain intact the Silage can be removed without difficulty.

ADDITION OF WATER.

Although it is generally recognised that it is necessary for the forage to retain living plant cells when it is put in a silo or stock, if good Silage is to be made, it is now known that these living cells are not absolutely essential to success. Providing suitable bacteria are present, and sufficient moisture is contained by the forage, Silage of similar composition to that made in the ordinary way can be produced without the assistance of living cells. First-class Silage has been produced by inoculating sterilised forage with suitable bacteria, and making up its moisture content.

It has been known for some time that forage cut and dried, and then put in a silo with adequate water, will make a good Silage. About the same weight of water as the weight of the dried forage is necessary to enable the material to be adequately packed together, and to lead to sufficient fermentation to properly preserve it.

If for any reason the forage to be made into Silage has become too dry, it should be damped with water whilst being put in silo or stack, and enough water must be used to ensure the proper packing of the material. The amount of water to use varies with the dryness of the forage, and whether it is being stored in a receptacle or stack. There is practically no danger of using too much water when stack silage is being made, and less damage will be done to the silage by an over-supply than if too little is used. Care must be exercised, however, when wetting forage being stored in a receptacle, because if too much is used the excess collects at the bottom of the silo and spoils the layer of silage which is flooded. If sufficient water is used to make up the moisture-content of the forage to about 75 per cent. there will be no surplus of water, and first-class silage can be made from rather dry material.

Saturating the top layer of Silage with water on completing the filling of a silo is sometimes practised to help compact the top layer, exclude the air, and reduce the losses by decomposition. This practice is of advantage when forage a little on the dry side is being stored in this way.

COVERING THE SILAGE.

It is sometimes claimed that it is worth while covering the top of the Silage to reduce losses of material, but in practice it is found that there is no covering which will prevent all loss, and when forage of sufficient succulence is used it soon decomposes and mats together on the top and makes a good seal, without excessive loss of material. A layer of wet cocky-chaff or wet straw makes a good seal on the top of Silage and reduces the loss of better forage, but is not worth considering for the purpose unless easily secured.

If loose soil is to be used for weighting the Silage it is sometimes thought advisable to apply a thin layer of cocky-chaff or straw before putting on the weight, but considering that a few inches of the Silage must be thrown away in any case, the practice is hardly warranted.

WEIGHTING THE SILAGE.

First class Silage of even quality throughout the mass, which will keep for a long period of time can only be made if the material is regularly squeezed together in some way, and this application of pressure is essential whether the Silage is being made in overhead silos, pit or trench silos, or in stacks. In some high, relatively narrow vertical silos in which chaffed forage is stored as Silage, it is often considered a more economical proposition to leave the mass unweighted, although it is recognised that there will be more loss of material at the top, and for some distance down the quality will not be so good as at greater depths. The higher the silo the less the need for adding weights, because the weight of the material itself consolidates all forage except the immediate top layers.

In all cases of silage-making, except when being manufactured in earth pits or trenches, weights should be applied immediately on completion of putting the forage together. Some makers go so far as to say that when building stacks of Silage, wires, to which weights are attached, should be thrown over the stack each night, and remain in position until more material is to be put on the stack. This precaution probably leads to the manufacture of a better article, but the advantage gained is so slight where some forage is put on the stack each day, that the trouble necessary to weight the stack every night is not warranted. If periods of three days or more are to elapse between additions of forage to the stack, then the temporary weighting down with something attached to wires is justified. In the case of earth pits or trenches, sufficient material must be put in the silo, so that after settling and covering a slight mound remains, and to make certain of this the filling is completed by piling forage 4ft. or 5ft. above ground level. The Silage in these silos is usually covered and weighted with soil removed from the hole, and as the easiest way to put the soil in position is with a scoop, it is usual to allow the silage to settle for a few days before weighting.

The amount of weight required to properly consolidate Silage varies with the method of manufacture. In tall, relatively narrow, vertical silos, weights equalling about 100lbs. per square foot of top surface should be applied. In comparatively shallow pits and trenches the weights should be increased to about 200lbs. per square foot, whilst for stack Silage much more weight is required, and the amount should be between 300lbs. and 400lbs. per square foot of top surface if best results are to be obtained.

Numerous contrivances have been invented for replacing weights on Silag stacks, most of them consisting of wire ropes and winding gear, but it is generally recognised nowadays that constant pressure is necessary for best results, and that any system requiring daily attention can only be fairly satisfactory. The regular pressure required is secured for a certainty when dead weight of some kind is placed on top of the forage. For the purpose articles usually found on farms, such as stones, earth, logs, fencing posts, scrap iron, and bags of sand are quite suitable, as are also concrete and mortar blocks.

Probably there is no more suitable article to use for weighting down Silage than rough stones of a size readily handled and thrown by a man. Provided really large stones are not used they are easily tossed on to the Silage, are convenient for stacking, do not dirty the Silage, are readily thrown out of the silo or off the stack, and are not difficult to move from place to place if the Silage stack is not settling regularly. Earth has some advantages as a weight for Silage, and is particularly suitable for silos, but if to be used on stacks it is necessary to fix a framework of some sort near the edges to keep the soil in position, and even then it is extremely difficult to get sufficient weight near the outside of the stack. Wire-netting, timbers (such as railway sleepers, wired together), bags of sand, &c., all make suitable frames to hold the earth. The silo or Silage stack is a convenient place to store fencing posts, logs, and rough timber generally, and they all weight down the forage efficiently, but are rather heavy to handle, and often demand gear to aid in lifting to high stacks or silos. Concrete or mortar blocks make suitable weights, and last almost indefinitely if handled carefully.

To be able to calculate the weight being used by a given depth of any of the above-menioned materials the following figures can be used:—

TABLE II.—*Weights of Materials for Weighting Silage.*

Materials.	Weight per Cubic Foot.	Depth of Material to give Sufficient Weight per Square Foot.		
		Deep Silos. 100lbs.	Shallow Silos. 200lbs.	Stacks. 300-400lbs.
	About	About	About	About
Stones (and concrete)	140lbs.	9in.	17in.	26 to 34in.
Sand	90lbs.	13in.	27in.	40 to 53in.
Loam	80lbs.	15in.	30in.	45 to 60in.
Clay	70lbs.	17in.	34in.	51 to 69in.
Timber	60lbs.	20in.	40in.	60 to 80in.

It is as well to remember that really good Silage can be made with considerably less weight than is shown above, but the nearer these figures are approached the better the resulting forage is likely to be.

SWEET OR SOUR SILAGE.

Two distinct kinds of Silage are produced from all fodders suitable for storing as Silage according to the method of manufacture followed. On the one hand what is known as "sweet" Silage is made, or if other practices are followed the Silage will be "sour." Both types are good, but they each have their advocates, some of whom are very strong in their preference for their particular fancy.

"Sweet" Silage is obtained by allowing the temperature of the material to rise to somewhere about 120° to 130° F. before checking it by applying weights to squeeze out the surplus air. Whilst the Silage is being made this control of temperature is done by putting more forage in the silo or stack, and when all the forage is in, other materials are used as weights. The temperature rises to the desired extent by allowing the access of plenty of air into the mass of forage, and is prevented from exceeding the useful temperature by removing the oxygen. In practice no thermometer is used, and one is not necessary, because experience shows that in a climate such as that of South Australia, if from 3ft. to 8ft. of succulent forage is put in a silo or stack each day for a period of six to 12 days, and weights are applied immediately on completion of the silo or stack, "sweet" Silage of high quality will result.

When the temperature of the forage is not allowed to exceed 120° F. "sour" Silage is made. This is brought about by limiting the amount of air in the forage, and is done in practice by throwing the material being ensiled into the silo or stack as quickly as possible, and immediately weighting it down.

In all silos, and in most well-made stacks, sour Silage is found at the bottom, whilst the top is usually over-fermented, because of the presence of an excessive supply of air.

As foodstuffs, there appears to be little to choose between these two forms of Silage, despite the exaggerated statements of their particular advocates, and the type of Silage to be made will usually depend upon circumstances. If plenty of help is available, and it is desired to get the job of Silage-making out of the way, the forage will be thrown together quickly and "sour" Silage will result, but where the saving of time is not so important, and where labor is short, the job will last longer and "sweet" Silage will be made.

When making "sour" Silage, care must be exercised if immature plants or very sappy forage are being stored, because if the fermentation of such materials is delayed to too great an extent, butyric acid is formed in quantity after the completion of the fermentations leading to the formation of lactic and acetic acids. The presence of much butyric acid gives the Silage a very objectionable odor, which might lead to the tainting of milk, and livestock do not eat the forage at all readily.

In endeavoring to produce "sweet" Silage, overheating of the material through excessive aeration must be guarded against, for in extreme cases it will lead to charring the forage, and consequently heavy loss of material and lowered nutritive value. This will only happen if over-mature or partially dried forage is being stored without the addition of water, or if the filling of the silo or building of the stack is delayed for some days without weights being used to keep down the temperature.

In practice it is found that there is less danger of making mistakes when manufacturing "sweet" Silage, and, as it is also less objectionable to humans, and is favored by livestock, it is better to try to produce this form of Silage rather than risk securing a really good "sour" Silage.

FODDERS USED FOR SILAGE.

The erroneous notion that almost any vegetable growth will make good Silage still persists in many quarters, but it is far from the truth, and anyone embarking on Silage-making activities must remember that (1) only good fodder will make good Silage, and (2) the better the fodder the better the Silage made from it. Ensiling some few plants which are more or less useless as forage, because of spines and coarse, tough tissues, such as Wild Artichoke (*Cynara cardunculus*), Spear Thistle (*Cirsium lanceolatum*), Slender Thistle (*Carduus tenuiflorus*), Milk Thistle (*Silybum marianum*), Yellow Cockspur (*Centaurea solstitialis*), Maltese

Cockspur (*Centaurea melitensis*), Buckbush (*Salsola kali*), and Furze (*Ulex europaeus*), converts them into useful forage through softening the objectionable tissues. Some weeds which are disliked by livestock because of the presence of many hairs, or the possession of a disagreeable taste, are considerably improved when converted into Silage, particularly when they are mixed with better forage plants in the silo or stack. Despite these few happenings, Silage-making must not be looked upon as a method of *making* forage, and should only be considered as a means of *storing* fodders, so that they retain their succulence and much of their nutriment.

Remembering that most plants which are fodder for livestock when in the green state can be stored as Silage if handled in the correct manner, and that the better the forage to be conserved in this way the better the quality of the resulting Silage, the plants to be used for the purpose will depend wholly on what can be grown to best advantage in the particular climatic conditions obtaining. The principal considerations in this direction will always be yield, succulence, palatability, nutriment, flavor, and odor.

Relatively coarse, strong-growing forage crops, such as Maize, Sorghum, and Sunflowers, are ideally suited for conversion into Silage, and where they can be successfully grown, give higher yields of fodder than the finer-stemmed forage plants. Throughout the world Maize is the principal crop stored as Silage, and it is generally recognised that where this crop can be grown well others are not considered to any great extent, but in South Australia other crops are likely to be of more importance, because in most parts of the State heavy crops of Maize cannot be grown with certainty every year.

The principal forage crops that can be handled with advantage as Silage in similar conditions to those obtaining in South Australia are described below.

COARSE-STEMMED FODDER PLANTS FOR SILAGE.

Of the coarse-stemmed fodder plants capable of giving heavy yields of forage in our climate, Maize, Sorghum, Sudan Grass, and Sunflowers are the most important.

Maize.

Maize can be grown really well where irrigation water is available, but in other places is a rather uncertain crop. Where sufficient water is under control to permit of liberal irrigation, Maize should be sown in rows about 30in. apart, using about a bushel of seed and 2cwts. Superphosphate per acre, the seeding being done as soon as the soil has warmed up in the Spring—say in October. When the rows of Maize plants are visible the land between the rows should be cultivated with a horse-hoe. Whenever the plants require water, the land should be furrowed out with the horse-hoe, and as soon after an irrigation as the soil dries out sufficiently to admit of the tramping of a horse the furrows should be cultivated.

Sorghum.

There is very little difference in the quality of Silage made from Maize or Sorghum, and although the former plant usually gives the highest yield of forage, Sorghum can produce full crops on less water than can Maize. Where the irrigation water is limited, Sorghum seed can be sown in October in rows about 30in. apart, using about 12lbs. of seed and 2cwts. Superphosphate to the acre. The crop should be irrigated when required with as much water as is available, and the land between the rows should be kept cultivated.

Sudan Grass.

Sudan grass is an annual sorghum which produces several fine-textured stalks rather than a few coarse stems, as is usual with the ordinary forage sorghums. It grows well enough in all parts of the State receiving 25in. or more of average annual rainfall to give regular crops of forage for Silage. In really fertile soil in districts with about 30in. of average annual rainfall, it can be succesgrown by broadcasting seed at the rate of 10lbs. per acre in October, and applying about 1½cwts. of Superphosphate per acre, but in districts with lower rainfall better results follow drilling about 7lbs. seed and 1½cwts. of Superphosphate to the acre in rows about 30in. apart, and keeping the land between the rows well cultivated throughout the growing period of the crop.

SUNFLOWERS.

It is possible to grow good crops of Sunflowers on much less rain than is necessary for Maize or any of the Sorghums, and the crop also does better where the weather is too cold or the season too short for these warmth-loving crops. Sunflower seed, at the rate of 15lbs. per acre, is, during September-October, drilled into rows about 24in. to 30in. apart, and about 2cwts. Superphosphate per acre is drilled in at the same time. While the plants are small enough the land between the rows is kept cultivated by the use of a horse-hoe.

From "Making Silage in Manitoba."

Sunflowers make good Silage, and although not so palatable as that made with maize, dairy cows keep up their milk flow on this forage almost as well as on maize Silage. The illustration shows a crop of sunflowers which yielded 30 tons of green forage per acre.

CEREAL CROPS FOR SILAGE.

In those portions of countries with a semi-arid climate, which have no supplies of water suitable for irrigation, the cereals can be grown with more certainty than can any other kind of crop, and as all of the cereals can be converted into good Silage, this type of crop will always be important if Silage-making becomes popular. In South Australia all of the cereals—wheat, oats, barley, and rye—can be grown to produce heavy, luxuriant crops suitable for Silage, and little more is necessary to ensure success than to fallow the land well, use plenty of superphosphate, and sow the seed early.

WHEAT.

Early wheats, such as King's White, Sultan, or Felix, produce very heavy crops which make good Silage, and should be sown at the rate of 100lbs. to 120lbs. of seed with 2cwts. Superphosphate per acre. Strong-growing wheats, such as Ford, Daphne, and German Wonder, should be seeded at the rate of 90lbs. to 100lbs. per acre. With all Wheats it is essential that they be seeded early in the season if they are to produce the very heavy crops required. When the seeding season opens in April the mid-season wheats can be sown, but in those years when the opening rains do not come before mid-May only very early varieties should be sown.

OATS.

Of the varieties of Oats commonly grown, Sunrise, Algerian, Lachlan, Bathurst Early, and Early Burt are all suitable for Silage crops, and should be seeded as early as possible at the rate of 80lbs. to 100lbs. per acre.

BARLEY.

Both Roseworthy Oregon and Shorthead Barleys make sufficiently luxuriant growth for Silage if started early in the season. They should be sown at the rate of 60lbs. to 70lbs. per acre.

RYE.

Rye is the best cereal to grow for Silage in cold wet locations and on sandy soils. All varieties make strong growth if germinated early, but of those known in this State, perhaps Giant Winter would prove the most suitable.

MIXED CEREALS.

Mixtures of the cereals generally make stronger growth than the separate kinds when grown alone, and these mixtures make first class Silage. Ford or German Wonder Wheat can be mixed with Sunrise, Algerian, or Lachlan Oats, and King's White Wheat and Early Burt Oats mature together. In wheat and oat mixtures grown for Silage about a bushel of seed of each should be used per acre. King's White Wheat can be mixed with either Roseworthy Oregon or Shorthead Barley, using about 50lbs. Wheat and 40lbs. of Barley to the acre. King's White Wheat, Early Burt Oats, and Roseworthy Oregon Barley can be mixed together at the rate of 40lbs., 30lbs., and 30lbs., respectively, and that quantity used per acre.

LEGUMINOUS CROPS FOR SILAGE.

Where a large assortment of forage plants can be successfully grown it is usual to look upon the fine-stemmed leguminous plants as being too good to convert into Silage, and they are cured and stored as hay. In an agricultural country with rather severe climatic conditions, however, where only a limited number of fodder plants grow luxuriantly, this does not apply, and if succulent feed is to be provided for the farm livestock throughout the year, portion of any forage crop which will grow well, whether it be a legume or not, must be stored as Silage. It is recognised that in making Silage of leguminous plants the loss of protein—the most valuable of the constituents of a foodstuff—is very great; still, it is usually worth while, because without succulent feed full returns cannot be secured from farm animals, and more particularly from dairy cows.

The leguminous crops which can be successfully grown in the State, and which can be converted into Silage of high quality, are Lucerne, Subterranean Clover, and Field Peas.

LUCERNE.

In all portions of South Australia where irrigation water is available and where the soils are of a non-acid type, Lucerne gives heavy yields of forage. The crop also grows well enough to enable growers to cut it several times during the season, even without irrigaton, in many places where the watertable is not too far from the surface. Although there is fairly heavy loss of nutriment in manufacture, Lucerne makes first class Silage, and whilst being fed with it dairy cattle require no proteinous concentrates. The best Lucerne Silage is made if the crop is cut when it has just reached the full-flowering stage and is chaffed into a silo, but good Silage is made from this crop whether it is stored in an overhead silo, trench, pit, or stack, and whether it is chaffed or preserved whole.

SUBTERRANEAN CLOVER.

Where conditions are favorable Subterranean Clover produces heavy crops of forage which can be manufactured into a really high-class Silage. Strong growth is made by this crop in almost all soils situated in countries where the climate is of a cool temperate nature, and where the average rainfall is 20in. or more per annum. This clover does not require much lime in the soil, as is usual with most clovers, but it will not make strong growth unless plenty of phosphatic fertiliser of some kind is applied.

FIELD PEAS.

The only leguminous crop which can be grown for a certainty in the principal wheat-growing districts of this State, *i.e.*, those districts receiving 18in. or more of average annual rainfall, is Field Peas. This crop when well grown makes first-class Silage, but because of the length of its stalks and their tendency to become tangled together, it is a very difficult crop to handle with ordinary harvesting machinery. Seed should be sown in May in most districts, at the rate of two bushels per acre, with the addition of 1½cwts. of Superphosphate.

PASTURE PLANTS AND WEEDS FOR SILAGE.

The pastures which follow the cereal crops are usually composed of plants which make really good Silage. The commonest pasture mixture which is to be found in the Wheat-growing districts of the State consists of a mixture of Burr Clover (*Medicago denticulata*), Barley Grass (*Hordeum murinum*), and Cape Dandelion (*Cryptostemma calendulaceum*), the proportion of the different plants varying according to season, but however the mixture might vary, really good Silage can be made from the growth. To get good results from this pasture, it should be cut and ensiled at about the time that the Barley Grass is heading.

In some cultivated districts, Wild Oats (*Avena fatua*) grow in association with Burr Clover, Barley Grass, and Cape Dandelion, and in others it is the predominating weed which follows cereal crops. Wild Oats make really good Silage if cut after heading and before seed is formed, and where this plant forms an important part of the growth to be stored as Silage, the time of cutting is decided by the maturity of the Wild Oats.

The Binder with canvasses removed makes an excellent machine for cutting pasture crops for Silage, as all material is left in narrow windrows easily picked up for carting to silo or stack. Used by Mr. J. H. Dawkins, Gawler River.

Weeds with spines like the thistles, or with tough fibres like buck-bush and furze, make very fair Silage if mixed in the silo or stack with good forage plants. Weeds such as mustard, charlock, turnip, &c., with objectionable flavors, should be used sparingly for Silage making, but provided that they do not form more than about 15 per cent. of the mass are converted into fair forage.

Very succulent plants such as rape, kale, cabbage, silver beet, beet tops, &c., are seldom stored as Silage, but it is possible to do so with some success if they are packed in alternate layers with cereal straw, or other dry forage.

YIELDS OF CROPS GROWN FOR SILAGE.

The yields of crops of all kinds vary very considerably according to conditions and treatment, and as it is desirable to get very bulky crops for conversion into Silage, and as coarseness of stem is not a disadvantage, every effort should be made to encourage the crops to make strong luxuriant growth. In this climate every advantage should be taken of available irrigation water, because very heavy crops of summer-growing forages can be procured, and be stored for use in the winter, when the supply of green fodder is short. With all crops being grown for Silage the soil should be thoroughly prepared before seeding, and where irrigation is not practised the land should be bare-fallowed beforehand. At seeding time liberal applications of Superphosphate should be given, for without it no crop gives full growth in these conditions. Plenty of seed should be used, particularly with the cereals sown in the Autumn, as the competition of plants close together encourages them to grow upwards with more rapidity, and over-luxuriance is not a disadvantage in a Silage crop. As most annual plants likely to be grown for Silage continue to increase in weight for a week or so after flowering, in this climate, higher returns will be secured per acre, if the crops are cut about 8 to 10 days after flowering.

The following table gives some idea of what can be expected from the principal Silage crops which can be successfully grown in South Australia.

TABLE III.—*Weights of Silage Crops.*

YIELDS TO BE EXPECTED UNDER NORMAL FARMING PRACTICES IN SOUTH AUSTRALIA.

Silage Crop.	Yield Per Acre. Tons.
Maize, Sorghum (irrigated)	20 to 30
Maize, Sorghum (not irrigated)	9 to 12
Sudan Grass	8 to 12
Sunflowers	12 to 25
Wheat (on fallow)	6 to 10
Oats (on fallow)	6 to 10
Barley (on fallow)	5 to 8
Rye (on fallow)	6 to 10
Peas	4 to 7
Subterranean Clover	5 to 9
Pastures (following cereals)	3 to 6
Lucerne (per cut)	4 to 7
Lucerne (during season)	20 to 30

SILOS.

A silo is a receptacle in which green forage can be stored so that it retains its succulence, without the whole mass decaying, and to fulfil these requirements such a receptacle must be fairly airtight, and so placed that water does not soak through the sides into the material stored. Naturally the more perfect the silo as regards being airtight and so also watertight, the better the final product, and the lower the percentage of waste.

Originally silos were simply holes dug in the ground, but these were improved upon by using masonry on bottom and sides, and later further improvement was made by building the silos wholly above ground. The latest development has been the manufacture of Silage without the help of a silo, by storing the forage in open stacks.

No matter whether the silo be an earth pit, or a pit lined with masonry, or an overhead silo constructed of masonry, wood, iron, composition, &c., there are certain essential features common to all. The bottom and sides should be impervious to air and water, otherwise much forage will be ruined, for when air is admitted moulds develop, and should water in quantity find its way into the silo, the material in the water rots down and looks like fully decomposed stable manure.

The sides of the silo should be perpendicular and as smooth as possible, and should contain no projections of any kind, so that in sinking the whole mass goes down regularly and evenly, for if this does not happen pockets of air are formed and the surplus air is not properly squeezed out of the mass, with much loss due to the growth of moulds.

The silo should have as few corners as possible, as corners make it difficult to pack the material tightly when filling, and they retard the sinking of the mass, so admitting air; the silo that fulfils this condition best of all is the circular silo.

The silo should be deep in proportion to its other dimensions; this, of course, means an increased weight on all below the immediate surface, and so a better expulsion and exclusion of air, less surface exposed to atmospheric agencies, and as silos are always emptied gradually, less surface exposed after each day's feeding is removed.

When the Silage is being removed for feeding to animals it is an everyday job, only sufficient being taken out of the receptacle each day for that day's feed requirements, and so it is of importance to see that when a silo is being constructed it be placed in close proximity to milking shed or other building where the animals are usually fed.

CAPACITY OF THE SILO.

In calculating the capacity of a silo it is usual to allow 50 cubic feet to the ton of Silage, and although this is somewhere nearly correct on the average, the variations due to height of silo, type of fodder, succulence of fodder, whether it be chaffed or whole, and the weight added, are really considerable. It is easy enough to make a fairly close estimate of the tons of Silage in a silo, by multiplying the surface area in feet by the depth of material in feet, and dividing the result by a figure between 45 and 55. This latter figure represents the space occupied by a ton of Silage, the lower figure being used if there is a mass of Silage 35ft. deep, and the greater figure for about 15ft. of Silage. It is more difficult to give a general figure for estimating the amount of Silage that can be put in a silo, because some receptacles can be heaped so far above the top that they are quite full of fodder after the mass has finished contracting, whereas others must be weighted down as soon as filled, and then the Silage shrinks a long way below the top. For silos with fixed roofs it can be taken that on the average one ton of Silage will be stored for every 70 cubic feet of air space in the silo, and for those with movable roofs or without roofs the figure will be somewhere between 45 and 60 cubic feet per ton of silage stored, according as the silo is filled or not.

In trench silos, which are always relatively shallow, and generally somewhere between 6ft. and 10ft. in depth, an allowance of about 60 to 65 cubic feet per ton is necessary. For instance, in a trench silo averaging 12ft. in width and 8ft. deep, every foot of length will hold about 1½ tons of Silage.

CAPACITY OF SILOS FOR KNOWN REQUIREMENTS.

When a decision has been made to erect a silo, it becomes necessary to calculate the amount of Silage required, and to construct a silo of sufficient capacity to enable this quantity to be manufactured. If the Silage is to be used for milking cows, the number of cows to be fed must be multiplied by the amount to be given each animal daily, and the result multiplied by the number of days during which the cows are to receive Silage. If the tons of Silage required be multiplied by 50 cubic feet per ton of Silage, the approximate cubic capacity of the silo will be found, and by reference to Tables IV., V., and VI., dealing with *capacities of silos*, the measurements of a sufficiently large silo will be seen.

TABLE VII.—*Quantity of Silage and Capacity of Silo for Known Requirements.*

Cows to be fed.	Silage per head per day.	Feeding period.	Quantity of Silage.	Capacity of Silo.
No.	Lbs.	Days.	Tons.	Cubic ft.

OVERHEAD SILOS.

Despite the fact that silos built above ground are much more expensive than those made below the surface, they have so many advantages over all other types that *Overhead Silos* have almost completely superseded *Underground Silos* in all places where much Silage is manufactured. Their outstanding advantage is that the daily job of removing the material is very much simplified, whilst at the same time the filling of these silos is not much more difficult than that of underground receptacles, because the machinery made for the purpose is very efficient.

Overhead silos can be constructed of any material which can be made airtight, and which is strong enough to withstand the considerable pressure from the inside, but they are usually built of concrete or wood, although steel, and kinds of masonry other than concrete, are sometimes used.

REINFORCED CONCRETE SILOS.

Reinforced concrete silos are the most permanent structures of all forms of silos, and although expensive are the most satisfactory from every point of view. A good deal of skill is required in building a cylindrical reinforced concrete silo, because specially constructed forms of wood or iron must be used, the reinforcing must be properly placed and fixed, the forms must be set perpendicularly each time they are shifted, a proper mixture of stone, sand, and cement must be used, each batch of the mixture must be brought to the same consistency, and be properly tamped so as to make a good solid wall, and a continuous doorway and shoot must be arranged for whilst building the silo. Extensive scaffolding is also necessary. The requirements are such that a skilled concrete man should always be employed when a reinforced-concrete silo is being erected.

The Materials Used.

As considerable strength is required in the relatively thin walls of a reinforced-concrete silo, it should be remembered that strong cement-concrete work is only produced when the best of materials are used.

Cement.—Only fresh cement of high quality should be used, and stocks held on hand should be stored in a dry place, and preferably on a wooden floor.

Sand.—Sharp sand binds together better than does rounded, water-worn sand, and so is to be preferred. The presence of clay, silt, or organic matter retards the proper setting of the cement, and so the sand should be free from these injurious substances.

Plan and details of a reinforced concrete silo 15ft. 6in. in diameter and 32ft. high. (Plan by J. Paull.)

Screenings.—The screenings, or crushed stone, should consist of regular-sized pieces, as odd large stones might interfere with the placing of the reinforcements. Really hard stone, such as quartzite, granite, or flinty limestone should be used.

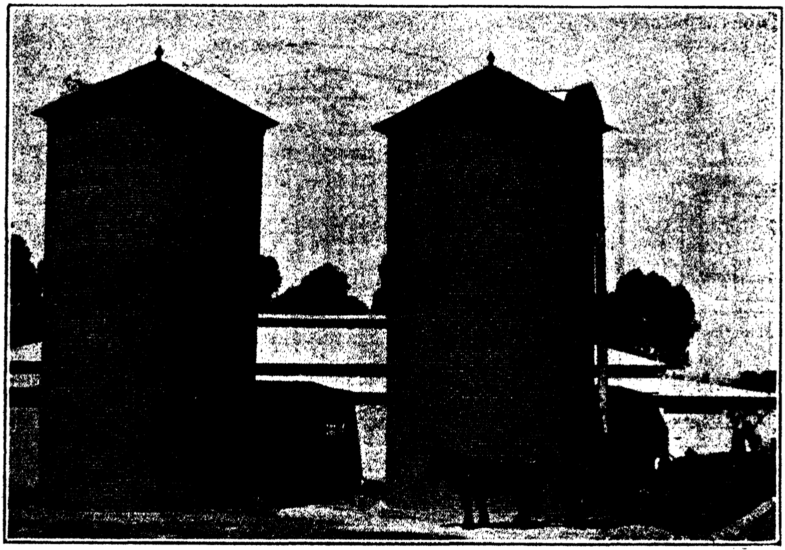
Water.—The water used should be clean and free from clay or organic matter in suspension, and should be reasonably free from an excess of saline matters, because some salts injuriously affect the lasting qualities of the cement concrete.

Reinforcing Material.—Because of its lack of strength, concrete work needs reinforcing, and for the purpose iron is one of the most suitable of materials to use. The iron to be used should be stout enough to be rigid and have no tendency to spring or stretch, and it must have surfaces rough enough to overcome the tendency to slip. If bright, smooth iron is used it is necessary to bend or twist it to secure the required grip.

The Mixture.

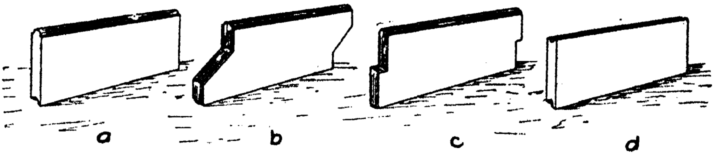
A good mixture for the cement concrete would consist of—

Two parts of ¾in. crushed hard stone.
Two parts of ⅛in. to ¼in. crushed hard stone.
Two parts of clean, sharp sand (not too fine).
One part cement.



A pair of Reinforced Concrete Silos at Roseworthy Agricultural College; showing the improved appearance following the use of corrugated iron on the outside forms.

The measured amount of crushed stone is spread in a ring on the mixing floor and made wet with water, and then the mixture of sand and cement, which had been previously mixed together in the dry state, is evenly distributed over it. The whole mass is now thoroughly mixed together whilst water from a watering can, or hose with a fine rose, is being applied in sufficient quantity to bring it to the right consistency. No more materials should be mixed at one time than can be used within a half-hour.



From "Silo Construction."

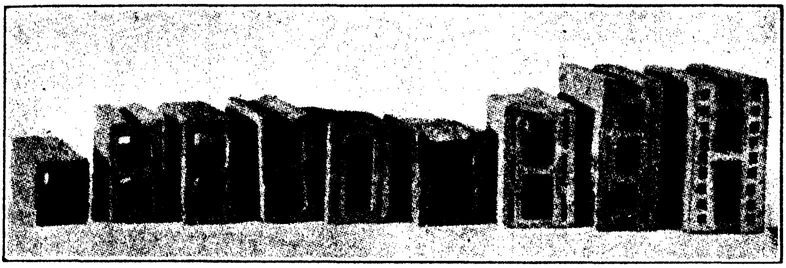
Reinforced concrete blocks for silo building; (a) book-shaped, (b) interlocking end joint, (c) stepped end, and (d) edges concave to be filled with cement mortar.

A much denser and smoother wall results if fairly moist concrete is put in the forms. Much less tamping is necessary with a mixture of such consistency, and the only disadvantage is that the forms must be left in position for a longer time than if a drier mixture is used.

The Reinforcements.

On really good ground the floor of the silo could be put down without reinforcements being used, but it is usually better not to take risks, and ¼in. rods crossed at right angles and tied together so that square meshes 9in. each way are made, are sufficiently strong for the purpose.

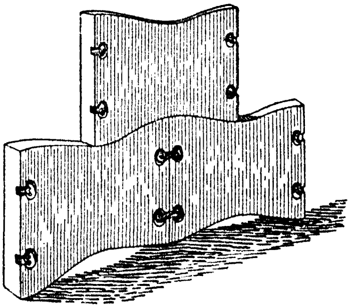
For a silo 15ft. in diameter and 30ft. in height, 5in. concrete walls are sufficient, and in such walls reinforcing rods of a diameter of 5/16in. can be used. The vertical rods which should always be tied on the inside of the horizontal rods, should be 12in. apart, whilst the horizontal rods will be spaced 4in. apart at the bottom with the spacing between rods gradually widening to 10in. at the top.



From "Silo Construction."

Hollow blocks made of burnt clay suitable for building walls of silos, provided plenty of bands are placed around walls to help withstand the inside pressure.

In a silo 25ft. in diameter and 40ft. high, the vertical rods should be of ⅜in. material spaced about 12in. apart. The bottom 9ft. to 10ft. of the walls will be reinforced with ½in. rods placed horizontally and spaced from 6in. apart at the bottom to 7½in., and from that height upwards ⅜in. rods are sufficient, the spacing between them gradually increasing from 4in. to 12in. at the top.



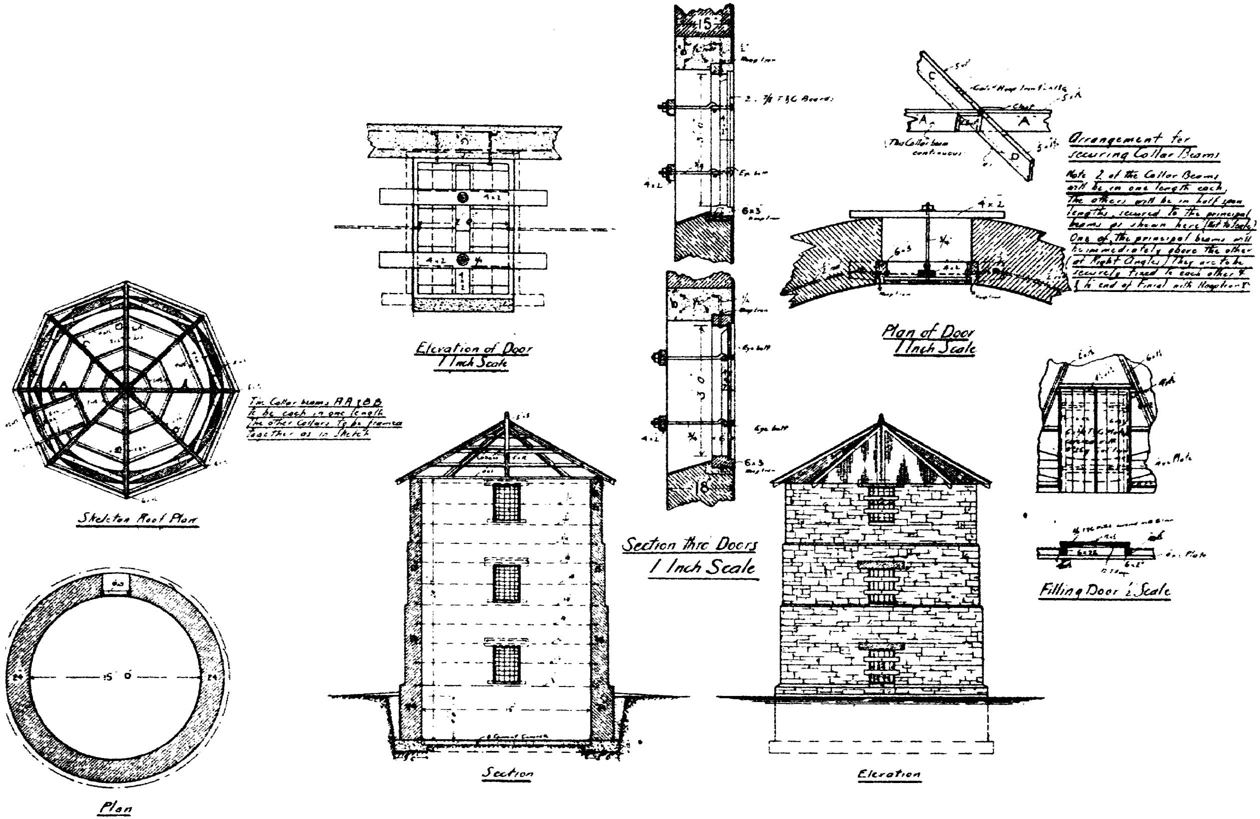
From "Silo Construction."

Shaped reinforced concrete blocks for silos, with ends of reinforcing steels exposed for coupling blocks together with clips.

All rods should be tied with No. 16 black tie-wire to all other rods that they touch. The vertical rods should be securely fixed to the reinforcements of the bottom. Wherever rods have to be joined they should have their ends turned over, and be overlapped a distance at least 40 times their diameter, and be securely bound together with tie wire; for instance, ⅜in. rods should be overlapped a distance of 15in.

Details of continuous doorway, roof, ladder, &c., are better seen in the accompanying plan of a cement-concrete silo.

C



Note 2 of the Collar Beams will be in one length each. The others will be in half span lengths, secured to the principal beams as shown here (Not to Scale.) One of the principal beams will be immediately above the other (at Right Angles.) They are to be securely fixed to each other & to end of Finial with Hoop Iron.

The Collar beams AA & BB to be each in one length. The other Collars to be framed together as in Sketch.

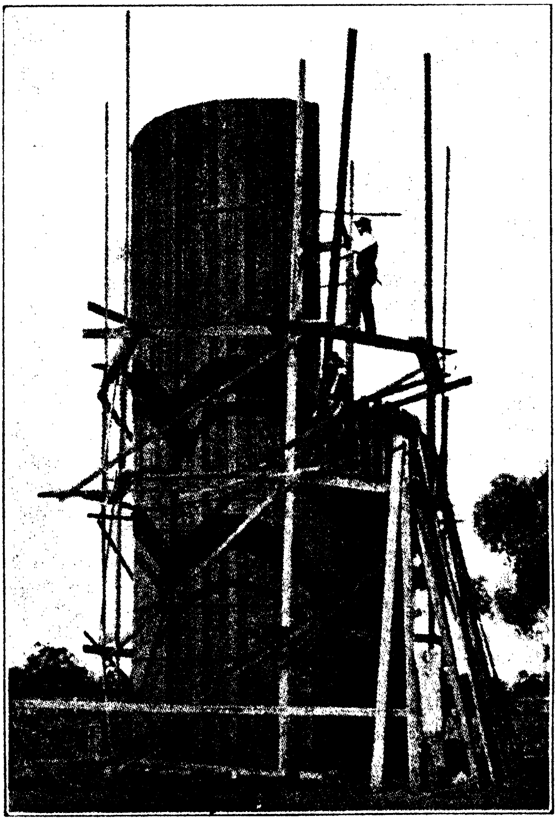
Plan and details of a masonry silo 15ft. in diameter and 24 ft. high. (Plan by J. Paull.)

STONE, BRICK, OR MASONRY BLOCK SILOS.

Overhead silos made of stone, bricks, or blocks are not quite so satisfactory as those made of concrete, but where it is more convenient to erect this form of masonry silo quite good results can be secured if care is shown when building. The chief difficulty with stone is to get the walls strong enough to withstand the inside pressure without having very thick walls. To get best results cylindrical silos should be built, and to keep down the amount of material used the walls should be stepped. Strength of walls will be maintained if iron hoops in the form of tightening bolts are placed around the silos in several positions. In a 25ft. silo the bottom quarter of the wall should be about 24in. thick, the next quarter about 18in. thick, the next about 15in., and the top quarter about 12in. If two hoops are put around each section, such a silo should prove quite satisfactory.

Burnt bricks and hollow tiles can be used in a similar manner to stone, and the same care is necessary to ensure sufficient strength in the walls.

Cement-concrete blocks of various patterns are used for making silos, and provided they are well strapped up with hoops which are never allowed to become excessively loose, they are well suited for the construction of this kind of receptacle, and are much lighter than ordinary masonry silos, because the walls are so much thinner.

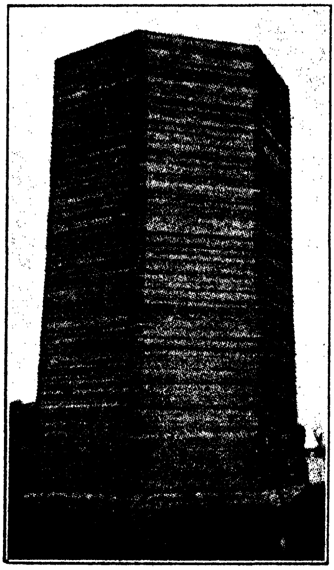


From Victorian Department of Agriculture Bulletin No. 45.

Erecting a wooden stave silo of 6in. by 1¾in. T and G timbers standing on end. The structure is kept together by ⅝in. bands, about 3ft. apart.

WOODEN SILOS.

In all places where timber is plentiful silos can be constructed of wood which prove quite suitable for the manufacture of silage, and are considerably cheaper than masonry silos. The great majority of wooden silos are what are known as stave silos, and are cylindrical in shape, and made with timbers from 4in. to 6in. in width placed vertically, and kept in position by hoops. The timbers are the full length of the silo where it is possible to secure such wood, but otherwise two lengths are used, being careful that the joints of adjoining pieces are not broken on the same horizontal line. When made of tongued and grooved staves of good quality timber, and when care is shown in keeping the hoops tight, such silos can be made to last 20 to 25 years. The hoops are of ½in. to ⅝in. rods, from 10ft. to 15ft. in length with long-threaded ends, and joined together with lugs against which the tightening nuts rest. The silos are almost invariably placed on a low masonry wall as a foundation, and when completed are anchored with guy ropes.



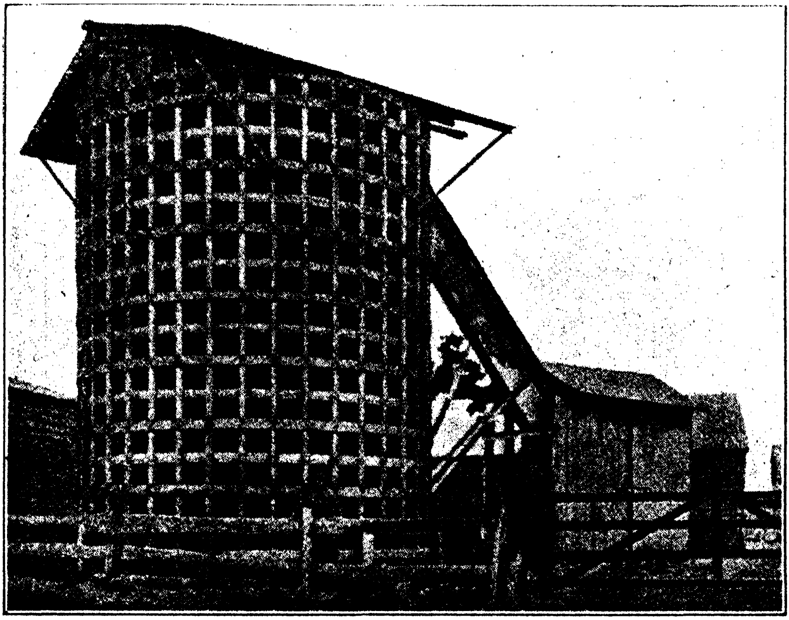
From "Silos and Silage in Colorado."
Easily constructed wooden silo where timber is plentiful. They are usually made of octagonal or hexagonal shape, and the inside is generally lined with some impervious material.

Home made wooden silos are easily constructed where timber is plentiful, and are made of octagonal or hexagonal shape, by placing the timbers horizontally. Material about 2in. by 4in. is used, and the pieces are cut to a shaped pattern, and the ends are halved before putting them in position. These silos are usually lined with such materials as weather boards placed vertically, cement plaster, or plain galvanized iron.

Wooden silos are never likely to be of importance in South Australia, because the lack of suitable timber means that they are very expensive, and the damage done to the wood by the severity of our Summer climate makes their upkeep much too costly.

WOOD AND IRON SILOS.

The acids developed in Silage attack iron fairly readily, and so it is not a really suitable material for the construction of silos, but it is easily handled for this type of structure, and if annually coated with a preservative like tar, pitch, or bitumen will last for many years. The easier way to make a silo in which iron plays an important part is to line a circular or sixteen-sided silo with 24-gauge galvanized iron on a wooden frame, the uprights and horizontals being spaced to suit the size of the sheets of iron being used. Such silos should be erected on a prepared masonry foundation.



From Victorian Department of Agriculture Bulletin No. 45.

A wood and iron silo constructed of 4in. by 2in. hardwood posts and 4in. by ¼in hoops fixed alternately on the inside and outside of the posts. The lining consists of plain galvanized iron of 24 gauge.

MASONRY PIT SILOS.

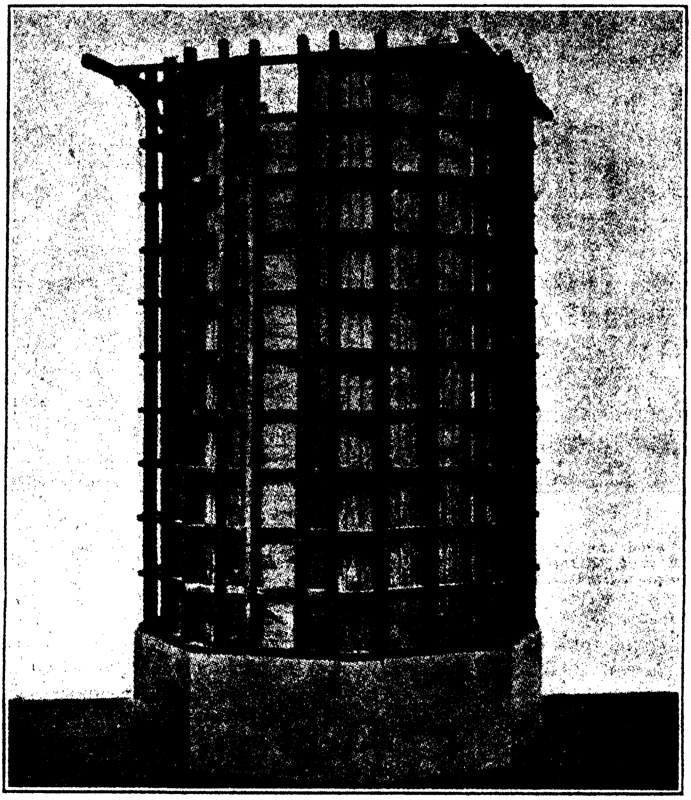
At one time pits lined with masonry were specially constructed for the making and storing of Silage, but now-a-days it is usual to erect an overhead silo when such a receptacle is required. Masonry pit silos are a great improvement on the earth pit, in that the bottom and sides are made air-tight and water-tight, and the smooth perpendicular sides facilitate the compacting of the mass of forage. The disadvantage of this form of silo, as against the overhead silo, is that the daily requirements of Silage must all be lifted out of the pit. This type of silo can be conveniently utilised when constructed in a steep hill or high bank, because a continuous doorway is made on the open side of the silo, which facilitates the emptying of the pit, and the filling is done readily by running the conveyances carrying the fodder to be ensiled on the top-side of the high land.

Any kind of masonry, such as cement concrete, stones, bricks, blocks, &c., can be used for the facing of pits, and where the walls are backed up by earth there is no need for great thickness, the principal need being just sufficient strength to prevent cracking.

TRENCH SILOS.

When it is desired to construct a silo and money is short, or when succulent feed is to be stored as an insurance against drought, there is no better way of doing it than in a trench silo. A first-class trench silo can be constructed with the ordinary tools and implements to be found on average farms, and if it be done during a slack period of the year it is almost wholly a question of labor, and calls for no actual outlay of money. As an insurance against drought, there are few better and more economical ways of storing fodder in times of plenty, and the silage made in trench silos keeps in really good condition for many years. At the Agricultural Society's Royal Show held in Adelaide in 1914, a very nice sample of Silage was exhibited which had been stored in an ordinary earth trench for over 20 years at Strathalbyn.

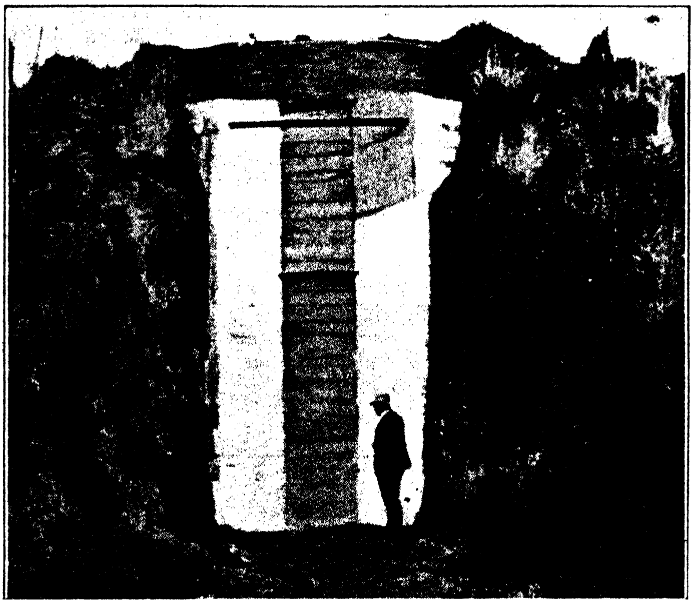
A trench varying from 10ft. to 14ft. in width at the top and from 6ft. to 10ft. in depth makes a suitable silo, if the texture of the soil and subsoil is sufficiently good for the walls to hold together when the trench is empty. The ends of the trench should have sufficient batter to allow the conveyances carrying the forage to enter the trench, and for the purpose the grade should be at least 2ft. to each 1ft. of depth. For instance, if the depth of the trench is 10ft., the top length of the trench should be at least 40ft. greater than the length of the bottom. The sides of the trench should have a slight batter, but if the soil is good enough to hold together in a trench 10ft. deep the bottom width should be only 3ft. less than top width, whilst in a shallower trench the difference in widths could be reduced to 2ft.



From "Silo Building and Ensilage Making."

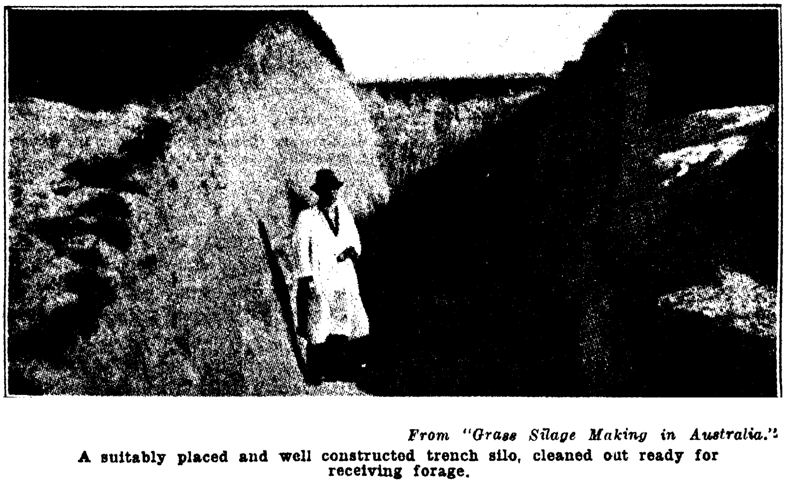
A wooden frame silo lined with weatherboards placed vertically. Such frames lined with sheet iron make fair silos, provided they are annually coated with tar, pitch, or such-like resistant substance. Sixteen-sided receptacles are better than those of octagonal shape.

The chief consideration when deciding on the site for a trench silo is the drainage, because it is essential that water does not enter the silo, either from the surface or underground. The best location for such a silo is on a ridge or hillock, where the surface water can readily be led away, and on such places the underground water-table is usually farther from the surface than on the flat ground.



From "Ensilage on the Farm."

Earth pit silos are somctimes the most suitable receptacles to make for the storage of Silage, and are convenient when made in a bank or hillock. The illustration shows a pit silo in an earth bank, with the open side concreted and a continuous doorway provided.

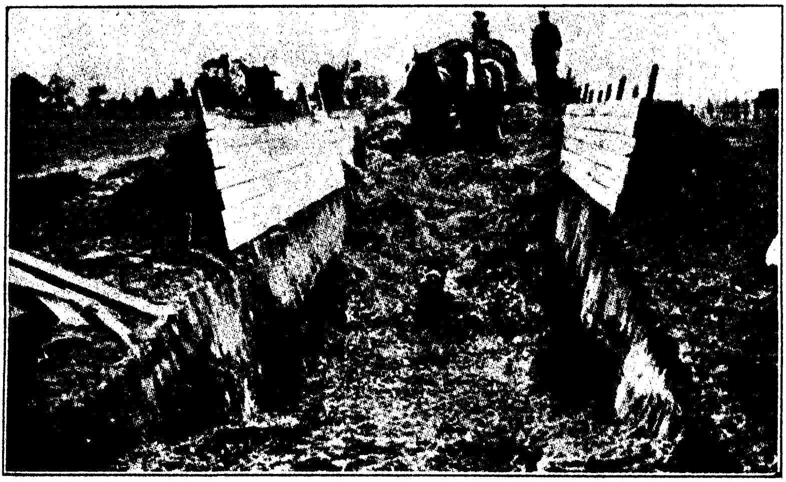


From "Grass Silage Making in Australia."

A suitably placed and well constructed trench silo, cleaned out ready for receiving forage.

The depth of the trench depends on the distance from the surface of the underground water-table, the type of soil and subsoil, and the purpose for which the Silage is being made. If the water-table permits, the trench can be extended to about 10ft., but it rarely pays to exceed this depth, because of the difficulty of sinking the trench, and the trouble of removing the Silage. Where the soil and subsoil hold together so that only a slight batter of the sides is necessary, the silo can be made of any convenient depth, but if there is a danger of the sides caving in the trench must of necessity be kept shallow. If the silo is to be filled and emptied annually, as is the case when used for dairy cows, it can be excavated to the full 10ft. in depth. If, however, the silage is to be used as an insurance against drought, and as such only required occasionally, it is usual to make trenches only about 6ft. or 7ft. deep.

Practically all of the work connected with the sinking of a trench silo can be done with a plough and scoop, but to facilitate the sinking of the Silage during manufacture, the sides should be finished off with a pick. Because the construction of a trench silo is largely a matter of labor rather than outgoing expenditure, it is looked upon as a "poor man's silo," but such silos are only warranted so long as drainage of underground water is not necessary, much time is not absorbed in sinking through rock or other obstructions, and the soil is not so sandy or gravelly that retaining walls are necessary, and if any of these disadvantages exist it is usually better to erect an overhead silo.



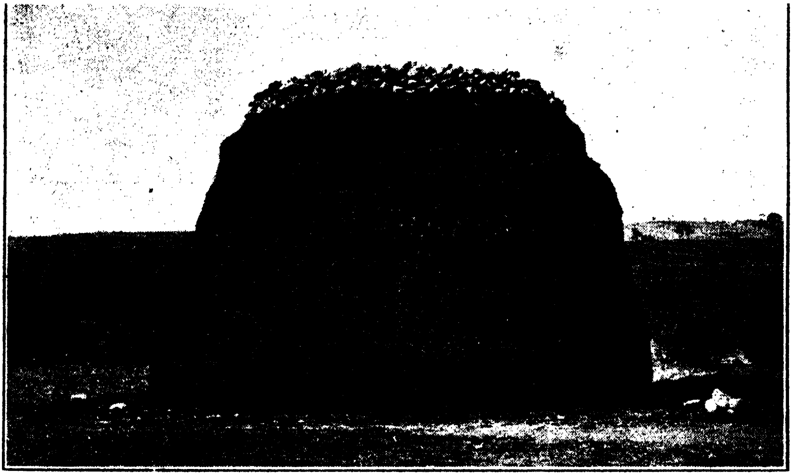
From "Grass Silage Making in Australia."

When filling a trench silo the conveyances carting the forage should help in consolidating the material by running over the material already lodged in the silo.

STACK SILAGE.

The simplest and cheapest method of making Silage is to dispense with the silo and make a stack of the succulent forage at a convenient spot near the farm buildings or out in the field where it was grown. The great advantage of this method of producing Silage is that it does away with the necessity of providing expensive receptacles to hold the forage, but it must be remembered that the losses of material during the process of manufacture are much greater under this system than where silos are utilised. The cured article from a stack properly constructed is just as good as from the best silo, provided the stack has not stood for too long a time. Stack Silage tends to dry out after a few years of exposure, particularly on the sides facing the direction of the prevailing winds, and so when it is intended to leave stacks of Silage for any length of time they should be built on sites where they will be protected from winds. In well built stacks properly protected from the wind, the Silage retains its succulence and feeding qualities for many years. The drying out of stack Silage does not render it useless, because it remains of fairly high feeding value, but the principal advantage of Silage, viz., its succulence, is lost.

Although the losses of material are fairly considerable with stack Silage, it can be confidently expected that where reasonable care is shown when building the stack, first class Silage weighing 70 per cent. of the weight of the green forage put into the stack will be secured. Besides this, nearly all of the apparently spoilt material on the sides and top will be readily consumed by "dry" cattle and sheep, so the actual waste is not so enormous.



A circular stack of Lucerne Silage at Wood's Point, showing the bottle shape assumed on settling, due to keeping the outside edge much higher than the centre during building operations. Under this system of stack building no difficulty is experienced in keeping the weights in position, and the outside is so consolidated that the waste is considerably reduced.

One of the principal advantages of making Silage in stacks is that the forage is stored whole, and if cut with a binder the sheaves are stacked without cutting the bands, and so its manufacture is mainly a matter of labor, and does not demand expensive machinery.

The removal of the Silage from stacks is also a simple matter, as the material is readily chopped out with a squaring axe, and is always friable enough to be easily handled.

THE MAKING OF STACK SILAGE.

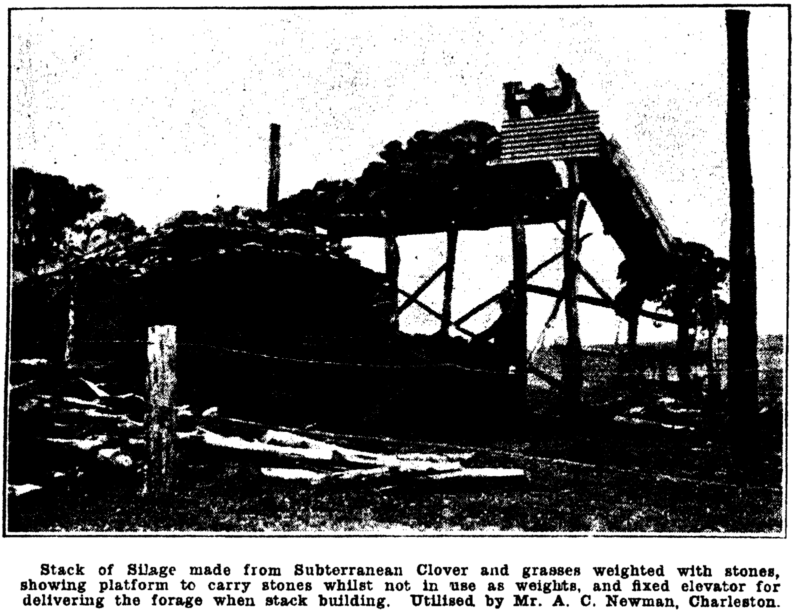
The stack can be erected near the farm buildings, or as is more often the case, in the field where the crop of forage to be ensiled was grown. In selecting the site for the stack it is necessary to avoid hollows likely to fill with water, and if it is possible to choose a spot where the stack will be protected from the prevailing winds so much the better.

The forage can be placed directly on the surface of the ground in most places, but there is sometimes a saving of waste of good forage if straw or such-like material is spread on the soil, before the first load of forage is distributed. On no account should materials be placed under the stack which will admit of the circulation of air, such as posts, wooden dunnage, stones, &c., because by so doing the loss of forage is considerably increased.

When deciding on the size of the base of the stack it is first necessary to estimate the amount of material to be stored as Silage, and to make quite certain that the base is not too large for the quantity available. Where there is not sufficient height of material in a Silage stack the loss is increased out of all proportion to the quantity of material. Whatever the diameter of the stack the aim should be to finish with a stack from 6ft. to 8ft. high, after it has completely settled. To get somewhere near this desired height the following allowances should be made:—

TABLE VIII.—*Size of Base of Silage Stack.*

Green Forage.	Silage.	Diameter of Stack.
Tons.	Tons. (Approximate.)	Feet. (Approximate.)
30	21	10
45	31	11
60	42	12
75	52	14
90	63	15
120	84	18
150	105	20

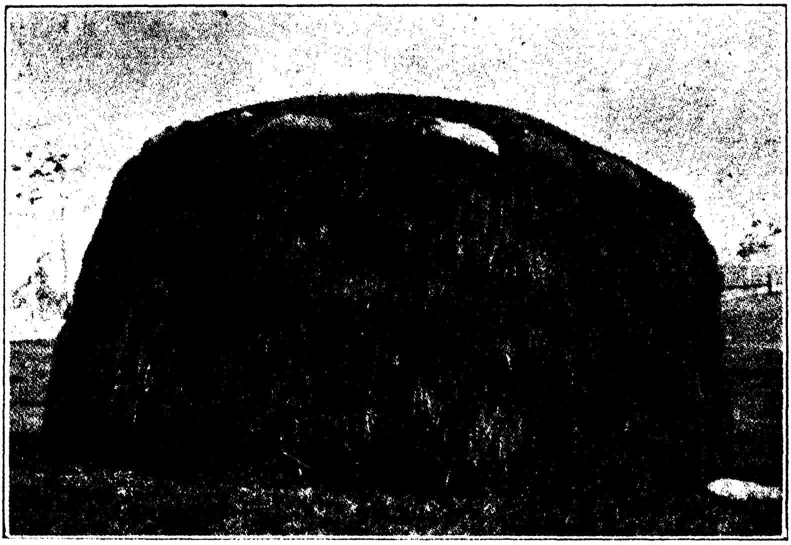


Stack of Silage made from Subterranean Clover and grasses weighted with stones, showing platform to carry stones whilst not in use as weights, and fixed elevator for delivering the forage when stack building. Utilised by Mr. A. C. Newman, Charleston.

Circular stacks are the most suitable where relatively small quantities of Silage are to be made, because they are much easier to build, and the losses are proportionately less than from rectangular stacks. Rectangular stacks are more suited for the storage of large quantities of forage, for when opened on one end there is less liability to the development of moulds and decay whilst using the Silage, than if a wedge-shaped piece is cut out of a large circular stack.

When building the stack it is usual to cart enough material on the first day to make the stack from 6ft. to 8ft. high, and then to place more fodder on the stack each day, arranging the carting so that it takes from 6 to 12 days to complete the stack. In practice it is found that if the temperature of the stack keeps rising, and the stack itself keeps sinking, it is essential to put more material on each day, or else to weight down the stack until again ready to start cutting and carting. Experienced Silage-makers can tell by plunging the hand into the material whether it is hot enough to require more fodder, but for beginners it is better to keep a thermometer in a piece of ordinary gas-piping let into the Silage. If the temperature rises above 120°F. more fodder or weights should be added, and this must be done before the temperature reaches 130°F. As a general rule it will be found that if from 3ft. to 6ft. of forage is added to the stack every day, a first class Silage will be made, but it should be remembered that immature, sappy forage heats up much slower than does more mature and drier forage, and that in cool weather less material is put on daily than in warm weather.

If the forage to be used is not all at the same stage of maturity, the drier, more mature portions should be cut first and put on the bottom of the stack, and the immature, sappy portions be left for the top of the stack. If handled in this way the drier stuff will be improved by the extra pressure and the soaking into it of the juices of the top layers.



From "Livestock Bulletin," 1/6/31.

When more suitable material is not available, bags of soil placed around the edges of a Silage stack are effective in keeping soil used for weighting purposes in position.

Throughout the building of loose material into a stack, the centre should be kept much lower than the outside, and at completion the top should be finished off with the centre only slightly above the outside edges. After the weight has been put on a stack built in this way, the centre sinks down more than the outside, leaving the top practically level, and cylindrical stacks assume a bottle shape, and have much less waste around the outside than where the centre has been kept high during building operations.

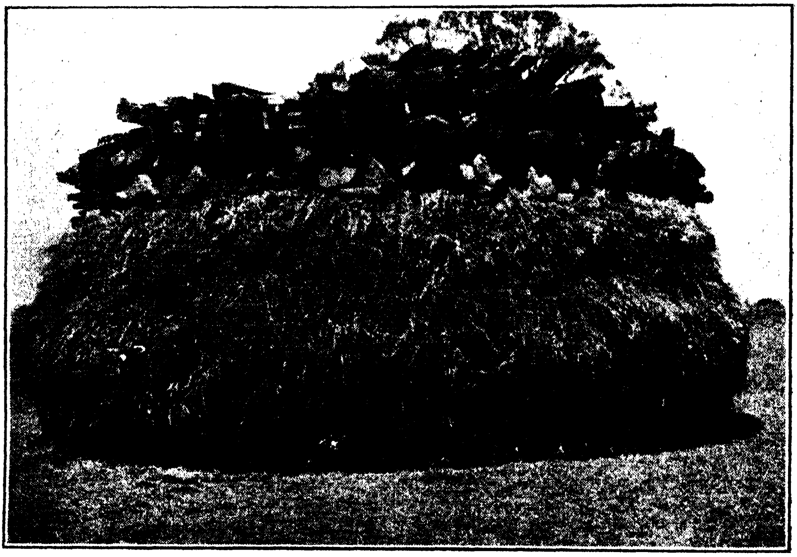
Frequently, during stacking operations, the outside of the stack should be strongly raked down with a fork, which reduces the openness, allows of the better shedding of water, and lowers the loss through over-decomposition.

When stacking coarse-textured forages like Maize, Sorghum, &c., which are liable to slip when the stack is settling down, it is of advantage to make rectangular stacks, and to erect a series of poles 3ft. or 4ft. apart along the line of the two long sides, and couple the tops of the opposite ones together in some way. If the forage is laid lengthways in the stack there will be no slipping of the material. To reduce loss on the ends of the stack the forage should be trimmed nice and square, during building operations.

As soon as a stack is completed it should be weighted down.

If weights are used that can be easily handled, they can be moved from place to place on the top of the stack if uneven settling is taking place, and in this way any tendency to fall over, or to bulge out in places can be overcome, with advantage to the appearance of the stack and the quality of the Silage.

Silage stacks should not be opened for 6 weeks or so after completion, and less mould develops on the cut faces if the stacks are kept closed for 10 to 12 weeks, when most of the fermentation processes will have ceased.



A circular stack of cereal Silage weighted down with fencing posts.

Most Silage stacks are too large to be able to take a layer off the whole of the stack every day for feeding to the livestock, and so it becomes necessary, in nearly all cases, to open one end of the stack and cut the Silage away to a vertical face. The smaller the area of this exposed face, and the shorter the period of time it is exposed the less waste there will be, and so it is essential for best results to take so thin a slice off the face that it will not be more than 3 or 4 days before the next slice is started. To cut a slice of Silage from the end of a stack there is no more efficient tool than a squaring axe, for it does the job rapidly, cleanly, and without strain on the operator.

ADDITION OF MINERALS WHEN MAKING SILAGE.

It is sometimes recommended to add Common Salt to the green forage as it is being put into the silo or stack, but this is likely to prove such a disadvantage that any good the animals might receive from the presence of the salt will be counteracted by the poorer quality of the Silage. Salt is usually added to forage to increase its palatability, but as properly made Silage is more palatable to farm livestock than any other foodstuff supplied to them, improvement in this direction cannot be looked for by the addition of salt. Further, successful Silage-making depends almost wholly on ferment and bacterial action, and as Common Salt retards these activities, poorer quality Silage is probably manufactured when this substance is added. The control of bacterial action by Salt is so great, that in wet countries where extreme difficulty is experienced in making hay, the partially dried material is stacked, liberally sprinkled with Common Salt, and cures into a brown hay, whereas without the salt it would have rotted down, or developed so much heat as to have fired.

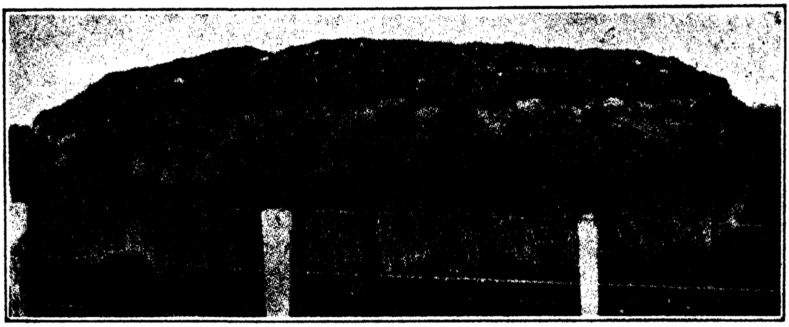
From "New Zealand Farmer," 1/10/31.

A well made stack of Silage, effectively weighted with soil, kept in position by heavy timbers.

From "Ensilage on the Farm."

Poles used to keep the earth in position when placed on a Silage stack to weight down the material.

Practically none of the ordinary foodstuffs contain sufficient minerals for the requirements of cows giving a good yield of milk, and this applies more particularly to lime and phosphorus. Some of this shortage can be made up by adding these minerals to the Silage whilst being put in silo or stack, and the presence of both lime and phosphorus encourages bacterial activities to such an extent that a much improved Silage should result. When Silage is being manufactured for the use of dairy cows, the sprinkling amongst the forage, during silo filling or stack building, of from 28lbs. to 56lbs. of finely ground Raw Rock Phosphate per ton of forage being stored, will improve the quality of the Silage, and considerably enhance its feeding value.



From "Ensilage on the Farm."

A strip of wire netting run round the eaves of a Silage stack makes a good barrier to hold soil in position when used as a weight to consolidate the forage.

UTILISATION OF SILAGE.

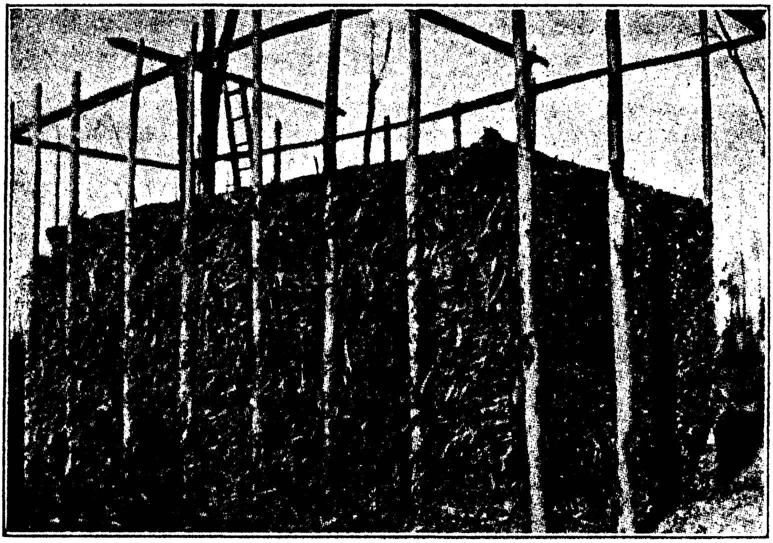
When considering the uses and value of most of the well-known feeding stuffs it is usual to study the composition of the fodders and then their digestibility, and on the figures disclosed calculations are made as to the economic value of the various materials, how much to give to the animals, and what kinds and proportions of fodders should be mixed together. This also applies to some extent when Silage is to be used, but Silage possesses so many other qualities which are not disclosed by chemical analysis or digestibility experiments that it is almost in a class by itself. The ordinary grazing farm livestock produce milk and meat to best advantage, and keep in better health, when allowed to get most of their food by grazing on good pastures, and Silage is the only foodstuff which gives results anywhere nearly approaching pastures. As a matter of fact good Silage,

From "Ensilage on the Farm."

This flat Silage stack is the result of building upon a base which was much too large for the available forage. The loss of Silage is considerably greater than if a reasonably-sized base had been arranged for.

when fed to milking cows and ewes with lambs, gives even better results than succulent green forage if the latter is cut and carted to the animals, particularly where the coarse-textured green forages are concerned.

The palatability of Silage is very high, and animals prefer it to all other ordinary foodstuffs, and perhaps of equal importance is the fact that it keeps up the appetite of animals receiving it, and so they consume more. All rations are improved by the addition of Silage, because all of the other constituents of the ration have their palatability increased, due to the presence of the Silage.



From "Australian Dairyman's Handbook."

Forage stacked as Silage between two lines of poles. Supported in this manner, coarse-stemmed plants, like maize, sorghum, &c., which are very liable to slip in ordinary stacks, can be stacked with perfect safety.

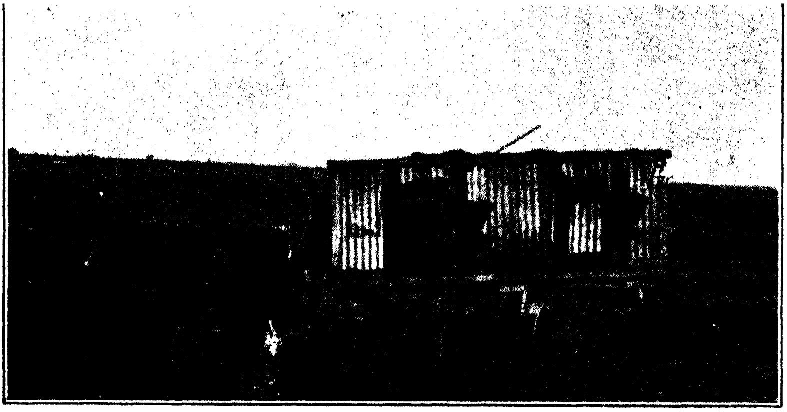
Silage is a wonderful foodstuff to keep animals in good health. It is always sufficiently laxative to maintain the digestive organs in good condition. If fed in the morning before animals are turned out to graze it prevents bloat to a very great extent. Cows and ewes have less trouble in giving birth to young if fed on Silage for a few weeks beforehand. Even in the driest times impaction is prevented when Silage is fed to the animals, and it is largely because of this that Silage has such great value in saving sheep and cattle in times of drought. There is no other bulky foodstuff to equal Silage in loosening the skin of animals, and in putting "bloom" on them. In all places where bone-chewing is a common practice with cattle, it ceases as soon as Silage is used as a part of the ration.

The amount of water taken in by animals in milk plays a big part in the quantity of milk secreted, and the feeding of Silage during the winter, when it is difficult to get animals to drink sufficient cold water, adds considerably to the amount of water consumed.

Although Silage can often be used to advantage by all farm livestock, because of its peculiar characteristics, it is more suitable for utilisation by dairy cows, ewes in stud flocks, and sheep and cattle in times of drought.

REMOVAL OF THE SILAGE.

When fodder has been placed in a silo it can be fed to livestock any time after the completion of filling the receptacle, but it is better to wait until the principal fermentative activities have subsided. In most silos the chief fermentations will be over a few days after weighting down the Silage, but although less active they still continue working for two or three weeks, and so for best results silos should not be opened for the removal of the Silage until the material has been in them for about four weeks, although it can be done much sooner if the fodder is urgently required. In the case of stacks of Silage it is better to leave them for 10 to 12 weeks before commencing to use the fodder, as there is then less tendency for Silage stored in this manner to go mouldy after being exposed to the atmosphere.



A useful lorry, with galvanized iron frame, used at Wood's Point for carting Silage to feeders in the fields. The doors, which are hinged at the bottom, drop on to the edge of the feeder, and act as shoots for guiding the Silage into the trough.

Although Silage will keep almost indefinitely in a silo, and for some years in a properly constructed and protected stack, the material rapidly deteriorates on being exposed to the air, and in warm weather becomes useless very quickly. Because of this, success with the making and using of Silage is closely connected with the careful removal of the fodder from the silo. When ready to use the material stored in a silo, the weights and any covering used are removed from the whole surface of the Silage, and the few inches of decayed fodder is taken to a place where the farm stock will not have access to it. A shallow layer of Silage is now scraped off the whole surface of the silo, and on no account should a hole ever be dug into the material itself.

Sufficient Silage is scraped off the whole surface each day to be used on the day it is removed, and in securing it care is taken not to loosen up any more material than is to be removed. In warm weather, when moulds develop rapidly on exposed Silage, 2in. to 3in. of material should be removed daily, but in cool weather 1in. each day is sufficient to make certain that it is always good, sound Silage which is fed to the animals. Silage keeps cooler in pits than in overhead silos, and so a shallower layer can be removed without damage to the Silage, and in most cases a 1in. layer daily is sufficient, even in warm weather. A few farmers go so far as to keep a waterproof sheet in the silo to cover the surface as soon as the day's supply of Silage has been removed, but this is hardly necessary with fully matured Silage from which a layer is being taken daily.

In preparing to remove the Silage from a trench silo, the soil used as a covering and weight should be cleanly removed from one end with a scoop, and the decayed portion down to the good fodder, which is usually about 3in. to 4in. deep, is cleaned off with a shovel. The material in the end of the trench should be cut out so as to leave a vertical face right across the trench. If it was practicable, the daily supply should be taken by cutting a layer from off the whole of the exposed end of the Silage, like cutting a slice of bread from a loaf, but this does not prove a reasonable proceeding unless very large quantities of Silage are to be used every day. Provided the time taken to complete the removal of the slice right across the exposed surface of the Silage is not too long, no great development of mould takes place, and it is usual to start a fresh slice about once a week. In very hot weather the period must be shortened, to keep down loss of material, and the risk of affecting the health of livestock, but, on the other hand, in really cool weather less haste is necessary. The squaring axe is a first-class implement for cutting off the slice of Silage, and once the cut has been made the material is easily picked up with forks for loading into bags or boxes, to be pulled to the surface by windlass or pulley and blocks.

Where small stacks of Silage have been built, or where large quantities of fodder are used daily, the whole of the stack is opened and a layer is scraped from the full surface each day. This rarely happens, however, and the Silage is removed in much the same manner as it is from a trench silo. The end of the stack farthest from the prevailing winds is opened, and a slice is cut off the whole of the exposed face. As stack Silage develops moulds much more rapidly after exposure than is the case in silos, the layer removed should be of such thickness that a fresh slice will be started every three or four days.

FEEDING VALUE OF SILAGE.

Although it is impossible to show in figures some of the advantages possessed by Silage as a feeding stuff for farm livestock, the actual feeding value as regards the production of milk, energy, muscle, fat, &c., can be seen in the chemical composition and digestibility figures presented in the next table, for several different kinds of Silage, with a few samples of green forages for comparison purposes.

Table IX.—*Feeding Value of Some Australian Silages.*

NOTES ON SAMPLES IN TABLE IX., WHICH GIVES "FEEDING VALUE OF SOME AUSTRALIAN SILAGES."

No. 1.—*Sorghum:* Silage made in a masonry pit at Roseworthy Agricultural College in 1914, a period of 4½ months elapsing between filling silo and using the fodder. Well weighted with fencing posts.

No. 2.—*Lucerne:* Made from chaffed Lucerne in December, 1930, in an overhead masonry silo at Wood's Point, the sample being taken at the end of May, 1931. Well weighted with stones.

No. 3.—*Barley and Peas:* Made by Mr. E. L. Miller, of Gawler, in a pit with cemented walls, from Six-rowed Barley and Field Peas grown in 1931, the grain of the former being in the doughy stage, and the pods of the peas well developed. Sample taken April 4th, 1932. No weights used.

No. 4.—*Barley and Peas:* Made by Mr. W. J. Dawkins, of Gawler River, in an overhead cement-concrete silo from Six-rowed Barley and Field Peas grown in 1931, the former having just headed and the Peas just forming pods. Sample taken April 4th, 1932. No weights used.

No. 5.—*Sunflowers:* Silage made in masonry pit at Roseworthy Agricultural College in 1921, the chaffed Sunflowers being put on top of Barley silage already in the pit. Well weighted with fencing posts.

No. 6.—*Barley:* Silage made in Masonry pit at Roseworthy Agricultural College in 1920 from Six-rowed Barley. Well weighted with fencing posts.

No. 7.—*Maize:* Hickory King Maize from a crop going 20 tons per acre put into silo in autumn, 1931, at Nowra, New South Wales, and sample taken in September, 1931. Quoted by Mr. J. N. Whittet in *Agricultural Gazette of New South Wales*, Vol. XLIII., Part 3.

No. 8.—*Wheat:* The crop was cut in 1931 by binder, in the flowering stage, by Mr. A. Sparrow, of Sandy Creek, and made into silage in a trench 6ft. deep, by stacking in sheaves, running over the material with every load, and covering with soil. Sample taken on January 6th, 1932.

No. 9.—*Barley:* Made by Mr. A. Sparrow, of Sandy Creek, in 1931, by stacking sheaves of Six-rowed Barley in a trench 6ft. deep, running over the material with every load, and covering with soil. Sample taken February 27th, 1932.

No. 10.—*Subterranean Clover and Rye Grass:* Made in a stack in 1931 by Mr. R. J. Trott, of Meadows, the pasturage consisting in the main of Subterranean Clover and Perennial and Wimmera Rye grasses, but there was also some Soft Brome and Silver grasses and Clustered Clover. Sample taken January 21st, 1932. Weighted with strainer posts piled to a depth of 4ft.

No. 11.—*Burr Clover and Wild Oats:* Besides Burr Clover and Wild Oats there was an appreciable amount of Wild Mustard in the pasturage used by Mr. J. Sincock, of Concordia, to make this silage. The material was rather over-mature when cut, and, although sprinkled with water during stacking, and fairly well weighted, the outside of the stack dried like hay, whilst the centre was charred. Put down in the Spring of 1931, and sample taken January 6th, 1932.

No. 12.—*Subterranean Clover and Grasses:* Made by Mr. T. Smee, of Charleston, in November, 1930, from pasturage containing about 20 per cent. Subterranean Clover, the remainder being mainly Sea Barley and Sterile Brome, but there were appreciable quantities of Yorkshire Fog, Soft Brome, and Silver Grasses. Too mature and too dry when put in stack, and although stones were used as weights, they were far from sufficient to properly compact the material together. Sample taken May 18th, 1931.

No. 13.—*Subterranean Clover and Grasses:* The pasturage used by Mr. A. C. Newman, of Charleston, to make this silage in November, 1930, contained about 30 per cent. Subterranean Clover, the remainder consisting of Sterile Brome, Soft Brome, and Silver Grasses, and some Spear Thistles. These very spiny thistles, often known as Scotch Thistle, are readily eaten by cattle when converted into silage. The crop was a little on the dry side, and although weighted with stones, more weight could have been used with advantage. Sample taken May 18th, 1931.

No. 14.—*Subterranean Clover and Grasses:* About 75 per cent. of this pasturage, grown by Mr. S. H. Andrew, of Charleston, consisted of Subterranean Clover, the remainder being made up of Sterile Brome and Soft Brome, with some Perennial Rye grass and Rib grass. Crop green and succulent when stacked in early November, 1930, and fairly well weighted. Covered with straw before stones were put on to weight it down. Very little waste at top or sides. Built in eight days. Sample taken May 18th, 1931, from near bottom of stack.

No. 15.—*Wheat:* Made by Mrs. E. Hartmann, of Monarto South, by stacking sheaves of wheat cut at the flowering stage in October, 1931. Sample taken February 19th, 1932. Fairly well weighted.

No. 16.—*Oats:* A round stack was built by Mr. C. S. Nankivell, of Mudla Wirra, of sheaves of Oats and a little Six-rowed Barley, cut in the milky stage, in the Spring of 1931. Sample taken January 6th, 1932. Fairly well weighted.

No. 17.—*Wheat:* Made by Messrs. Thomas Bros., of Monarto South, in October, 1931, by stacking sheaves of wheat cut in flowering stage, and sprinkling the material with water whilst being put together. Sample taken February 19th, 1932. Well weighted with stones.

No. 18.—*Wheat:* Made by the Farm Manager of Northfield Mental Home in the Spring of 1931, by stacking sheaves of wheat cut in flowering stage. Sample taken January 6th, 1932. Fairly well weighted.

No. 19.—*Burr Clover, Wild Oats, and Cape Weed:* The pasturage was made into silage by Mr. J. H. Dawkins, of Gawler River, by cutting it with a binder without elevator canvasses, and stacking the loose stuff. Put in stack in the Spring of 1931, and sample taken February 27th, 1932. Fairly well weighted.

No. 20.—*Paspalum dilatatum:* Made at Nowra, New South Wales, in the Autumn of 1931 from grass that had made rapid and luxuriant growth, with the seed head just formed, but not reached the flowering stage. Sample taken September, 1931. Quoted by Mr. J. N. Whittet in *Agricultural Gazette of New South Wales*, Vol. XLIII., Part 3.

No. 21.—*Subterranean Clover and Grasses:* Made by Mr. F. O. Ball, of Bugle Ranges, by stacking pasturage which consisted of a mixture of Subterranean Clover with Rye, Soft Brome, Sterile Brome, and Silver grasses, and some Cape weed. Stacked in November, 1931, and weighted, but insufficient weights were used. Sample taken March 15th, 1932.

No. 22.—*Maize:* This is an interesting sample of stack silage, in that the Maize was stacked by Mr. Watkins, of Fulham, in the year 1921. The top was covered over with earth, and was not opened until October, 1931. The color was still good, the texture rather powdery, and on the date of sampling—October 15th, 1931—it contained 82 per cent. moisture.

Green Forages: The analyses of green forages shown for comparison purposes are all of European samples, and are calculated from figures in "The Scientific Feeding of Animals," by O. Kellner.

The figures in Table IX. show very clearly the great differences that exist between the feeding values of different samples of Silage, and as all the instances given are of the one type of foodstuff, *i.e.*, succulent roughage, the figures are strictly comparable. The three figures of importance when estimating the value of the respective samples are those for ***protein, starch equivalent,*** and ***nutrient ratio*** because this type of foodstuff is generally used for the production of milk, or for maintaining animals in times of shortage of pastures. When the palatability of two foodstuffs of the same type is equal, a comparison between the *starch equivalents* of the two shows their relative values for maintaining or fattening animals. As *protein* is of great value in encouraging the secretion of milk, the quantity present decides how valuable, in this connection, any given foodstuff is likely to prove, but as the non-nitrogenous portions of the food are utilised to produce heat, energy, and fat, the relation between the *protein* and various *nitrogen-free substances*, or what is known as the *nutrient ratio*, is nearly as important as the actual content of *protein*.

Perhaps the best way to compare foodstuffs of the one kind is to study the *starch equivalent* figures first, which will show their respective values for fattening or for maintenance purposes, and then give attention to the combination of *starch equivalent* and *nutrient ratio*, to see which are the best for the production of milk and muscle. A foodstuff with a fairly high *starch equivalent* and a fairly narrow *nutrient ratio* is a much better fodder on which animals can produce milk and maintain their condition, than is one with a very high *starch equivalent* and a wide *nutrient ratio*, or one with a low *starch equivalent* and a very narrow *nutrient ratio*.

In comparing the Silages shown in Table IX., it will be seen that Sample No. 10 is of outstanding quality, having the really high *starch equivalent* of 13.0 per cent., and the very narrow *nutrient ratio* of 1 to 3.9. Although lucerne is a highly nitrogenous foodstuff, of first class quality for the production of milk, when fed as a green forage, and has the narrow *nutrient ratio* of 1 to 3.7, its *starch equivalent* is only 9.8 per cent., it is not nearly so good a general livestock foodstuff as is Sample No. 10. Again, Sample No. 22 has the very high *starch equivalent* of 13.6 per cent., but it is obviously a poor milk producer, because its *nutrient ratio* is only 1 to 12.4. The value of the addition of Field Peas to Barley is shown by comparing Samples Nos. 3 and 4 with Sample No. 9; the Barley silage shows only 9.8 per cent. as *starch equivalent*, and a *nutrient ratio* of 1 to 9.3, whereas the mixtures of Barley and Peas have nearly 1 per cent. more *starch equivalent*, and a *nutrient ratio* narrowed down to a little more than 1 to 6. The differences between Silages made from the one kind of forage are clearly brought out by these comparisons as can be easily seen if Sample No. 10 is compared with Sample No. 21. The latter has a *starch equivalent* of 9.6 per cent. against 13.0 per cent., and its *nutrient ratio* is 1 to 7.9 against 1 to 3.9. Further, the Wheat Silage in Sample No. 15, with its 11.3 per cent. of *starch equivalent* and a *nutrient ratio* of 1 to 6.4, shows to advantage when compared to another Wheat Silage, also from a stack, as represented by Sample No. 18, where the *starch equivalent* is 10.2 per cent. and the *nutrient ratio* 1 to 7.0.

These instances are sufficient to show that it is possible to compare foodstuffs of the same kind, if the composition and digestibility of all of them are known, and this information is essential before it is possible to put a value on the various foodstuffs which livestock husbandmen have to handle.

FEEDING SILAGE TO FARM ANIMALS.

All farm animals which ordinarily consume pasture plants are attracted by the palatability of Silage, and when it has been properly made they eat it readily, and in most cases do well on it. For some kinds of livestock, however, it has such disadvantages as to preclude it from ever becoming a prominent foodstuff for them. In a general way it may be taken that because of the losses in manufacture, the making of Silage is a fairly expensive operation, and as its outstanding advantage is the providing of a succulent foodstuff at times when the other available foods are dry, it generally proves economic only for those animals in urgent need of succulent foodstuffs. Because of this Silage can be looked upon as essential for dairy cows if the most is to be got out of them, useful for the ewes of high-class sheep studs, and very valuable for sheep and cattle in times of drought, but of considerably less value for horses, pigs, and poultry.

Silage for Dairy Cows.

For dairy cows to give maximum returns it is essential that they be provided with succulent feed throughout their lactation period, and in most localities this is only possible if some of the surplus green forage of the flush of the season has been stored as Silage for use in the time of shortage. Because of this, Silage is looked upon in some dairying districts as being essential if the cows are to prove fully profitable. Not only does Silage, fed when green feed is short, keep up the flow of milk, but it is a matter of common observation that even when good pastures are available, the addition of Silage to the cows' ration practically invariably leads to an increase in the quantity of milk produced. This happening often encourages people to claim that Silage should form part of the ration throughout the year, but there are few dairymen who go as far as this in the use of Silage.

Besides promoting an increased milk flow Silage is a safe feed, having a laxative effect on cows, and is particularly useful when fed before calving, in fitting the cow to calve with ease, and to clean properly after calving. It is a noted fact that cows fed regularly on Silage remain in better health than those not receiving it, no matter what other kind of feed they are provided with.

Silage will maintain cows in good condition even when they get no other feed, but when the cows have to supply milk, even the best of Silage is not an all-sufficient foodstuff. All Silages are too bulky for the amount of nutriment they contain, and they are usually too low in protein and mineral matter content to give best milk yields, and although the addition of first-class Lucerne or Clover hay would often raise the protein content sufficiently high, the mixture still remains too bulky for full results. To enable cows to consume sufficient fodder to keep up a full milk flow, and maintain body weight, it is usually necessary to add some grain concentrates to the mixture of Silage and leguminous hay. The next table gives some rations, including Silage, for cows of different weights, producing various quantities of milk of different quality.

TABLE X.—*Feeding Silage to Cows in Milk.*

Cows.		Silage.	Food Requirements per Day.			
				Grain Concentrates.		
Live Weight.	Milk Produced per Day.		Lucerne or Clover Hay.	If Milk Tests up to 3·5%.	If Milk Tests from 4% to 4·5%.	If Milk Tests 5% and over.
lbs.	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
700	10	21	7	—	—	—
	20	21	7	4	5	6
	30	21	7	8	10	12
	40	21	7	12	15	18
800	10	24	8	—	—	—
	20	24	8	4	5	6
	30	24	8	8	10	12
	40	24	8	12	15	18
900	10	27	9	—	—	—
	20	27	9	4	5	6
	30	27	9	8	10	12
	40	27	9	12	15	18
	50	27	9	16	20	24
1,000	10	30	10	—	—	—
	20	30	10	4	5	6
	30	30	10	8	10	12
	40	30	10	12	15	18
	50	30	10	16	20	24
1,100	10	33	11	—	—	—
	20	33	11	4	5	6
	30	33	11	8	10	12
	40	33	11	12	15	18
	50	33	11	16	20	24

The rations set out above would be varied according to circumstances. For instance, if Silage was plentiful and grain concentrates not readily available, more Silage and less concentrates would be used, or if the Silage was made from Lucerne or Clover, less leguminous hay would be required. It sometimes proves more economic not to purchase grain concentrates, and then the fodder given to the cows might consist of 40lbs. to 60lbs. of Silage per day, and what grazing they can get in the fields, or from 30lbs. to 60lbs. of Silage may be the daily allowance, together with all the leguminous hay that the animals will eat.

Silage does most good in keeping up the flow of milk, when the cow has not been allowed to go back because of the lack of succulent feed, and so dairymen should commence feeding Silage before the pastures have dried towards the end of the Summer, rather than wait until all succulence has left the grazing fields.

When commencing to feed Silage to cows for the first time in the season, it is as well to get them used to it gradually by giving about 5lbs. per head, twice a day, and then regularly increasing the supply until they are on a full ration.

To simplify the work, and to save time, it is customary with some dairymen to feed Silage to the cows while they are being milked in the bails, but this is not a good practice, because with certain samples of Silage there is a risk of some of the strong odor being absorbed by the milk. The correct time to give the cows access to Silage is immediately after milking, rather than during milking, or immediately before.

Silage should never be distributed on the surface of the ground for milking cows, but should always be given to them in feeders of some kind.

As the succulence of this kind of fodder is one of its greatest advantages, it should only be taken from the silo or stack immediately before giving it to the cows, or if the two daily feeds are to be removed in the morning, the allowance for the afternoon feed should be protected in some way so that it does not dry out.

SILAGE FOR OTHER CATTLE.

It is generally recognised that bulls should not receive too much Silage in their ordinary rations, but in most places it is considered quite safe to let them have from 12lbs. to 15lbs. per day, fed in conjunction with good cereal hay and a little grain concentrates.

Calves utilise Silage to good advantage, but should not have access to this kind of foodstuff until they are about two months old, after which time it is safe to let them have, twice a day, all they will clean up shortly after it is given to them. Silage is not all-sufficient for calves, and must be supplemented by good chaff and grain concentrates.

Ordinary, well-preserved Silage will maintain dry cows and steers in good condition, even though they receive no other fodder, and it is quite safe to feed to them all that they can eat, still they do better if Silage only forms part of their ration. A good ration for dry cows is 30lbs. to 40lbs. Silage and 6lbs. to 8lbs. leguminous hay per day, on which the animals will do well, and calve with ease.

In some countries it is usual to hand-feed fattening steers, and when this is the general practice Silage is frequently used as the principal roughage, and usually with good results. When stored as an insurance against drought, it proves most useful for cattle, because there is no foodstuff which keeps the suffering animals in such good health during these periods of extreme shortage of fodder.

SILAGE FOR SHEEP.

In this country Silage is used for sheep of two kinds—for ewes in valuable studs and for the ordinary flock in times of drought. When it is desired to have the ewes to lamb in the early Autumn, before the green feed has started, there is no foodstuff that helps the ewes more than does Silage. If fed to them some few weeks before they are due to lamb, the ewes keep in good condition, deliver big, well developed lambs, which make rapid progress from birth onwards. If there is some picking in the fields the Silage can be fed at the rate of 3lbs. to 4lbs. per ewe per day with excellent results, but if the dry feed is poor, a little grain should be put in the troughs with the Silage.

For ordinary flock sheep being fed in times of drought, 2lbs. to 3lbs. of Silage is sufficient when there is a picking in the paddocks, but when there is little dry feed about the quantity should be increased to about 4lbs. per head per day.

If fed to lambs they should be allowed to become accustomed to it gradually, otherwise they might scour when first given large quantities of it.

SILAGE FOR HORSES.

It takes so little mould or other fungi to upset the digestive system of horses, and Silage is so liable to contain such growths that this forage is not looked upon with favor by horse masters. If, however, the Silage is in first class condition with no sign of mould, it can be used as a part of the ration for resting horses. It tends to make working horses too soft, and is generally considered to be unsafe for brood mares.

If horses are gradually accustomed to it, they can usually make good use of about 15lbs. to 20lbs. of good, sound Silage per day fed in conjunction with good hay and some grain.

SILAGE FOR PIGS.

Silage cannot be looked upon as a good foodstuff for pigs, and at best can only take the place of pasture or other greenstuff in times of shortage. Pigs eat good Silage readily enough, but the waste of material is considerable, and it should only be given to them to keep them healthy when green feed and skim-milk are not available.

SILAGE FOR POULTRY.

When free from moulds, Silage is quite useful for poultry, and particularly for laying hens, but unless extremely large numbers of poultry were being handled it would not be economic to specially make Silage for them. On the other hand, when chaffed Silage is being removed from the silo for other stock, some of it could be given to the poultry if there was a shortage of green feed at the time.

SUMMARY.

1. Silage is the name given to luscious green forage preserved in such a way that it retains its succulence, palatability, and digestibility, whilst the word "silo" stands for the receptacle in which the Silage is made.

2. Silage is made by cutting forage plants when very green and succulent, and storing the forage under pressure, usually in air-tight receptacles, but sometimes in stacks.

3. The palatability and digestibility of practically all forage plants are increased by converting them into Silage.

4. When live plants are thrown together in a heap the cells continue to breathe, and if the heat evolved whilst using up the free oxygen is not sufficient to kill the cells, they begin extracting oxygen from their own materials.

5. After the death of the cells, ferments and bacteria become active, and continue until the heat developed, or the acids formed, kill their activities.

6. Successful Silage-making depends on controlling these ferments and bacteria so that there is neither too much heat nor too much acid formed. It is done by regulating the amount of air in the forage, which is brought about by hastening or delaying the putting of the forage together, and then by applying weights to squeeze the surplus air out of the mass, and prevent its re-entry.

7. The principal physical changes brought about in Silage-making consist of changing the color of the forage to a brownish shade, flattening out the plants, developing characteristic flavors, which vary from acid to nutty, and the evolution of a peculiar odor.

8. Silage cannot be made without fairly considerable losses of feeding material.

9. The forage to be preserved as Silage should be cut whilst green and sappy, and be put into the silo or stack whilst still fresh and unwilted.

10. Cereals should be cut for Silage soon after heading, strong leguminous plants when the bottom leaves are beginning to yellow, clovers and similar plants after they have passed full bloom, maize when the grains are becoming glazed, sorghums when the bottom leaves are drying, sunflowers when showing color in most flower-heads, and grasses when well out in head.

11. Immature growth tends to make mushy Silage, whilst over-mature crops are usually too dry to make good Silage without the addition of water.

12. Rain falling during Silage making does no damage to the forage.

13. A nutty-flavored Silage with pleasant odor, is usually made when some forage is put in the silo for each of 6 to 12 days, and weights are applied as soon as the filling is completed. A minimum of 3ft. and a maximum of 8ft. should be put in the silo each day.

14. When the silo is filled quickly and the weights added soon, greener, but more acid and less attractive Silage is made.

15. Best quality Silage can be made whether the forage is chaffed or left whole. Chaffing facilitates the filling and emptying of silos, whilst whole material is essential for stacks.

16. Forage that is low in moisture content, because of approaching maturity or from exposure, should be moistened with water whilst being converted into Silage.

17. The amount of weight required to properly consolidate Silage varies with the method of manufacture. In tall, narrow silos 100lbs. per square foot of top surface should be applied, in shallow pits and trenches about 200lbs. per square foot, whilst for stacks the weight should be about 300lbs. to 400lbs. per square foot.

18. Dead weight gives better results than mechanical appliances requiring frequent attention.

19. "Sweet" Silage is made when the temperature is allowed to approach 130°F. before being checked, whilst "sour" Silage results if the temperature is not allowed to reach 120°F.

20. There is little to choose between "sweet" and "sour" Silage.

21. Only good fodder will make good Silage, and the better the fodder the better the Silage made from it.

22. The plants to be used for Silage will depend wholly on what can be grown to best advantage.

23. The sides of a silo should be as near perpendicular and smooth as possible, and should contain no projections, so that in sinking the whole mass goes down regularly and evenly.

24. The silo should be deep in proportion to its other dimensions.

25. Overhead silos have so many advantages over all other types that they have almost superseded underground silos where much Silage is made.

26. Overhead silos can be constructed of any material which can be made airtight, and which is strong enough to withstand the considerable pressure from inside.

27. Reinforced concrete silos are the most permanent structures of all forms of silos, and are the most satisfactory.

28. Overhead silos made of stone, brick, or masonry blocks are quite satisfactory, provided iron hoops, in the form of tightening bolts, are placed round the structure in several positions.

29. Where timber is plentiful, satisfactory wooden silos can be made.

30. Silos lined with iron last for years if coated annually with tar, pitch, or bitumen.

31. Pits lined with masonry make convenient silos, particularly if constructed in a steep hill or high bank.

32. Trenches from 6ft. to 10ft. in depth are suitable for making Silage, particularly for the storage of forage as a reserve for times of drought.

33. The cheapest method of making Silage is in stacks, and the forage is just as good as from the best silo, provided that the stack has not stood for too long a time.

34. When commencing to build a Silage stack care must be shown to make quite certain that the base of the stack is not too large for the material available.

35. Plenty of weight must be used on a stack of Silage, and it should be put in position as soon as the stack is completed.

36. Salt should not be added when making Silage, but the addition of 28lbs. to 56lbs. of finely ground Raw Rock Phosphate per ton of fodder will improve the Silage and benefit livestock.

37. Good Silage gives better results than green forage if the latter is cut and carted to the animals.

38. Silage is more palatable than other ordinary foodstuffs, and keeps up the appetite of animals so that they consume more.

39. The addition of Silage to a ration increases the palatability of all constituents of the ration.

40. Silage keeps animals in good health, loosens their skins, puts "bloom" on them, prevents impaction, and overcomes the bone-chewing habit. It is particularly valuable in reducing trouble during parturition.

41. Silage can be fed to livestock any time after the completion of the filling of the silo, but the quality is better if left for about a month. In the case of stacks they should be left unopened for 10 to 12 weeks if possible to do without the fodder.

42. In removing the Silage a shallow layer from 1in. to 3in. at least should be scraped off the whole surface of the material in the silo each day, without loosening any not to be removed. A hole should never be dug into the Silage.

43. In trenches and stacks the exposed end of Silage should be vertical, and a thin slice be taken off the whole face. The slice should be of such a thickness that it will not take more than three to six days before a fresh slice will be started.

44. When forages of the one kind are to be used for (*a*) maintenance or fattening, or (*b*) milk production, they can be compared by studying a combination of *starch equivalent* and *nutrient ratio*. A high *starch equivalent* means a good fattening or maintenance foodstuff, a narrow *nutrient ratio* means a good milk producer, but a forage with a fair *starch equivalent* and a fairly narrow *nutrient ratio* is a much better foodstuff on which animals can produce milk and maintain their condition, than is one with a very high *starch equivalent* and a wide *nutrient ratio,* or one with a low *starch equivalent* and a very narrow *nutrient ratio.*

45. The addition of Silage to a cow's ration practically invariably increases the flow of milk.

46. Cows fed regularly with Silage keep in better health than those not receiving it.

47. All Silages are too bulky for the amount of nutriment and minerals they contain for cows producing much milk, and so for all high-yielding cows, some leguminous hay, such as Lucerne or Clover, as well as some grain concentrates, should be added to the Silage.

48. Cows in milk should be started on Silage before all other fodders have gone dry.

49. Cattle should be gradually accustomed to Silage by commencing with about 5lbs. twice a day.

50. Silage should be given to cows immediately after milking, and not just before.

51. Bulls should only receive from 12lbs. to 15lbs. Silage per day.

52. Calves can be started on Silage after they are two months of age.

53. Silage is a first-class forage for cattle during times of drought, keeping them in better health than most other foodstuffs.

54. When ewes are to be lambed when pastures are dry, Silage is a really good forage for them, particularly if they are started on it some weeks before lambing.

55. There is no better fodder for sheep in times of drought.

56. Only the very best samples of Silage, quite free from moulds, should be given to horses, and even then it should only form part of the ration.

57. Pigs eat good Silage readily, but waste a lot of it.

58. When free from moulds poultry do well on Silage, but it would not be economic to make it specially for them.

REVIEW OF SOUTH AUSTRALIAN VINTAGE 1931-32.

[By J. L. Williams, Lecturer in Viticulture, Roseworthy College.]

The 1931-32 season proved a very disappointing one for South Australian viticultural interests. The season opened very favorably, with good rains during the wet months (May-September), but October was practically rainless, and towards the latter part of that month two frosts were experienced, the districts principally affected being Clare and Barossa. In these districts considerable damage occurred in both wine and drying varieties. Some damage also occurred in the South Wine Districts and in the Irrigation Settlements, but here the damage was mainly confined to locations subject to late Spring frosts, whereas in the Clare and Barossa Districts the damage was more general. This was the most severe frost experienced for many years in the Non-irrigated Districts.

The early termination of the wet season was particularly unfortunate, as many growers in the Non-irrigated Districts were unable to commence ploughing at the usual time owing to the wet condition of the soil during the period July to September and later found ploughing almost impossible, due to the dry conditions in October. Considerable valuable soil moisture was lost in this way, and vine growth suffered as a consequence. Vineyards with stiff soils were the ones chiefly affected.

During the "growth period" of the vine (October-December) very little useful rain fell, particularly in the Barossa District, as the appended rainfall table will indicate; this also was reflected in the growth of the vine at the end of the season and considerably affected the ripening of the crop.

During the ripening period, January to April inclusive, another unfortunate set of climatic conditions prevailed. March and April were unusually wet, particularly in April, when from 2½in. to 4½in. fell. As a consequence, late ripening varieties such as "Grenache" and "Mataro" suffered considerably through the development of mould and a "Beaume" of above 13.5-14.0 was difficult to obtain. Some fruit was left on the vines, whilst the bulk of the remainder was only fit for distillation purposes.

Drying operations both in the Non-irrigated and Irrigated Districts were greatly hampered, and the quality of fruits on the racks at this stage was considerably lowered, although fruits dried earlier in the season were of an even high standard. In this connection the "standard dip" as advocated by the C.S.I.R. played a prominent part. Late picked fruits, however, had to be processed by using the "hot caustic soda dip" in order to speed up the drying. Growers with dehydrators were making full use of them and many other hydrators were hurriedly installed. This serves to illustrate the necessity for this form of drying, for late pickings, in seasons where adverse drying weather prevails.

Table I.—*Showing Useful Autumn and Winter Rains for Seasons* 1930-31.

In these tables Clare figures are taken to represent the Clare and Watervale Districts, Tanunda the Barossa District, Morphett Vale the Southern Wine Districts, and Waikerie the River Irrigation Settlements respectively.

A glance at the above tables will serve to show that the 1931-32 season opened with good Autumn and Winter rains from approximately 5in. to 6in. better in the Non-irrigated Districts than in 1930-31. This resulted in the subsoil being wetted to a reasonable depth and providing a fair reserve of soil moisture. These were the best subsoil rains received for several seasons and gave growers early cause for optimism concerning the 1931-32 Vintage, and in many instances figures approaching a record were forecast.

However, Nature decided otherwise, and early forecasts had to be considerably modified as the result of a dry Spring and severe frosts. This set-back was later followed by unreasonable ripening weather, resulting in a further decrease in the quantity of fruit harvested as well as interfering with the quality, due to the fruit developing mould and taking up moisture. Despite these reverses the Government Statist (Mr. W. L. Johnston) forecasts an increase over the previous Vintage of 93,966 gallons or 0.93 per cent., based on returns of growers representing 90 per cent. of the previous season's total production. Mr. Johnston provides the following figures:—

FIVE YEARS' WINE STATISTICS.

Year.	Wine Made.			Wine Exported.	
	Total.	Distillation Proportion.	%	Overseas.	Interstate.
	Galls.	Galls.		Galls.	Galls.
1926-27	16,159,595	9,350,588	58	2,265,755	2,583,701
1927-28	12,820,733	6,849,284	53	2,856,806	2,216,875
1928-29	14,828,968	9,414,691	63	1,423,799	1,940,065
1929-30	12,406,017	6,954,436	56	1,840,986	1,910,965
1930-31	10,131,034	4,966,422	49	1,837,986	1,462,554
Five years' mean	13,269,269	7,507,084	57	2,044,977	2,022,832
1931-32. Estimated	10,225,000	(*a*) 5,828,000	57	(*b*) 2,869,747	Not available

(*a*) On average proportion of five years.
(*b*) Eleven months' record.

Early in the season some doubts were expressed concerning the ability of manufacturers for financial reasons and also for lack of storage to absorb the produce of the vineyards. Reduced yields, however, solved this difficulty effectively, if not satisfactorily.

Growers in the Barossa District have, for several seasons, experienced difficulty in selling their produce, and have been processing it co-operatively in privately owned premises. Sufficient success has attended their efforts to induce them to build a winery of their own in readiness for the next Vintage.

The present season has opened auspiciously, even better than the previous season, good soaking Autumn and Winter rains falling over Non-irrigated areas, providing ideal moisture conditions for bud-burst and a satisfactory reserve of soil moisture. Unfortunately the frost experienced in the Spring of 1931 has resulted in the vines in the affected areas being a tangled mass of watershoots. Such vines are but poorly supplied with fruiting wood, and this must affect the crop in the coming season.

We hope that the coming season will not be a repetition of the immediate past season as the growers of the dried vine fruits especially have suffered more than their share of the ironies of fate. A good season last year would have enabled growers to regain some of their losses of past years, the result of low prices.

Vine diseases last year, apart from meteorological disorders, were conspicuous by their absence, as was only to be expected in view of the dry Spring.

WHEAT PRODUCTIVITY CLASSIFICATION 1931-32.

[By H. L. SEMMENS, Acting Government Statist.]

With a view to ascertaining the extent of acreage producing very high and very low returns of wheat per acre, all wheat farms have been classified according to their productivity per acre. The accompanying return sets forth comparative details for the three seasons, 1929-30, 1930-31, and 1931-32.

Compared with the previous season, the total yield was 48,093,102 (34,871,526) bushels, averaging 11.81 (8.34) bushels per acre, and the agricultural areas rainfall, April-November, was 13.27 (11.31) inches. The more favorable season for 1931-32 is reflected in the higher yields:—3,488 (1,733) farmers, or 24.38 (12.35) per cent. harvested 18 bushels per acre and upwards, producing 37.86 (18.52) per cent. of the crop from 19.74 (7.22) per cent. of the total area sown. 39.87 (37.42) per cent. of the farmers harvested 9 and under 18 bushels, and 35.75 (50.23) per cent. less than 9 bushels per acre.

Of the 3,488 farms with average yields of 18 bushels and over, 1,577 were in the Central Division, 1,463 in the Lower North, and only 448 in the remaining four Divisions of the State. Of the 14,306 farms in the State, 9,192, or 64.25 per cent., harvested yields of 9 bushels and over, and 5,114, or 35.75 per cent., yields of less than 9 bushels.

Of the total of 5,114 farms under 9 bushels, the Murray Mallee and Western Divisions had 1,665 and 1,467 respectively. In these Divisions there were 301 and 160 farms under 3 bushels, 710 and 540 with 3-6 bushels, 654 and 767 with 6-9 bushels, and 702 and 1,230 with 9 bushels and over. During the last five seasons the total State acreage under wheat has increased 1,300,000 acres, of which 850,000 acres has been in these two Divisions, and the effect has been to reduce the average yield for the State.

The following are the details in Divisions:—

Divisions.	Average Rainfall April-Nov.*	Average Wheat Yield.	Wheat Farms with Yields of—			
			Under 9 bush.	9–18 Bush.	18 bush. and over.	Total.
	In.	Bush.	No.	No.	No.	No.
Central	16·92	16·26	881	1,796	1,577	4,254
Lower North	12·62	17·64	316	1,422	1,463	3,201
Upper North	9·85	9·76	610	549	178	1,337
South-Eastern	18·14	10·57	175	182	93	450
Western	12·57	9·26	1,467	1,092	138	2,697
Murray Mallee	10·36	7·55	1,665	663	39	2,367
Total, 1931-32 ..	13·27	11·81	5,114	5,704	3,488	14,306
1930–31 ..	11·31	8·34	7,052	5,253	1,733	14,038
1929–30 ..	9·57	6·40	7,833	3,675	1,688	13,196
1928–29 ..	9·39	7·79	7,094	4,619	1,673	13,386
1926–27 ..	13·40	12·84	3,558	6,284	2,896	12,738

* Rainfall average over Agricultural areas only.

Average Area of Wheat Crops per Holding.—Central 146, Lower North 275, Upper North 315, South-East 124, Western 422, and Murray Mallee 403 acres. Total State, 285 acres. There were 1,787 farms with less than 50 acres for wheat, and of those 850 were less than 20 acres.

Productivity of Wheat Areas, South Australia.

Comparative analysis of the productivity of wheat areas per acre for the seasons 1929-30, 1930-31, and 1931-32. Total average inches rainfall in agricultural areas (with April-November totals in parentheses), 1929 12.48 (9.57), 1930 1309 (11.31), 1931 15.11 (13.27).

ROUP.

Replying to the Secretary of the Appila Branch of the Agricultural Bureau, who asked for a reliable cure for roup in fowls, the Government Poultry Expert (Mr. C. F. Anderson) says:—"Remove the yellowish colored lumps by scraping away with a small piece of stick sharpened at one end. When the lumps have been removed, apply a little powdered bluestone to the affected parts. No relief will be obtained, however, until the lumps are removed. This disease is infectious, and all affected birds should be isolated. The roosting quarters should be cleaned up and sprayed with a 10 per cent. kerosene emulsion; also give a few drops of kerosene in the drinking water—just sufficient to leave a light film on top of the water.

CUTWORMS EATING LETTUCE.

Asking for the best means to exterminate small worms which are eating lettuce plants, the Secretary of the Wasleys Branch has been advised by the Chief Horticultural Instructor (Mr. G. Quinn) that if the pests are true cutworms—caterpillars which hide in the soil during daylight and come out at night and eat the plants—the remedy is a poisoned bran mash made by mixing in a dry condition 1oz. of arsenate of lead powder, or of paris green, in 3lbs. of bran; then dissolve several ounces of sugar or molasses in hot water and make this mixture of poison and bran into a thick mash. This mash is sown in small lumps on the ground around the plants. As this mash is poisonous to poultry or animals which might pick up the lumps, judgment is necessary in using it.

THE GREEN MANURING OF ORCHARDS AND A NEW GRASS FOR THAT PURPOSE.

[By EDGAR W. PRITCHARD, Dip.Econ., Agricultural Botanist.]

It is now well known that by continual cropping, the richest soil, as well as the poorest, will gradually become exhausted. In South Australia the first plant food to give out has been phosphates. This has been remedied by adding to the soil various forms of mineral phosphates, or bonedust. But there is ample evidence that another ingredient is now rapidly becoming exhausted. This is organic matter or humus. All virgin soils contain a certain amount of it, due to rotting vegetation, but this supply soon becomes used up by cultivation. For cultivation loosens the soil, and allows more air to circulate through it. The oxygen of the air then acts on the organic matter, and by the aid of the soil bacteria causes it to decay much more quickly, converting it finally into water, carbonic acid gas, and nitrates. This process, of course, greatly increases the fertility of the soil for the time being; but if the organic matter is not replaced, it becomes finally less productive than if not cultivated at all.

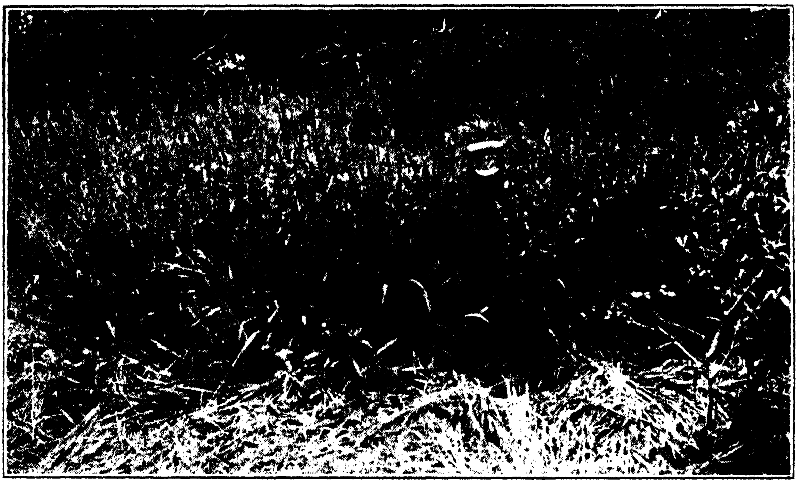

Fig. 1.—Purple Oat Grass, showing Dense Growth.

On farms where the crop rotation contains one year of pasture, or where a fair amount of stubble is ploughed in, the organic content of the soil may be maintained. In orchards, on the other hand, where clean cultivation throughout every summer is necessary, the humus content is apt to get very low, unless some special means is taken to renew it. This is sometimes done by means of stable manure, but that is not often practicable. So almost every orchardist has to rely on the ploughing in of green crops.

Now there are many ways in which a large content of humus is useful in orchard soils.

(1) It helps to hold the soil together in winter.
(2) It prevents it from drifting in summer.
(3) It makes the soil loose and, if heavy, easy to work.
(4) It helps it to hold more moisture, if light.
(5) It retains plant foods, and prevents them being washed out of the soil.
(6) It is necessary for the action of the soil bacteria in fixing the nitrogen of the air, and thus making it available as a plant food.

Further, a cover crop grown in the winter is the best means of holding the soil together, thus preventing washing in districts of heavy rainfall. And yet with all these advantages, green manuring is little practised in South Australian orchards, excepting on the Murray. What is the reason?

I have to thank the Horticultural Instructors for the following information on this point.

The first reason is the difficulty in getting the ploughing done and the crop put in in the autumn, before the heavy winter rains begin. And the second is that, in the hills district especially, the crop cannot be got sufficiently forward to plough in during the spring. This must be done by the end of August or the beginning of September, or there will not be sufficient moisture in the soil to cause the green stuff to rot./ In that case it will simply dry, and so keep the soil too loose and open throughout the summer, and thus dried out to a considerable depth. At the Blackwood Experiment Orchard, I am informed, these difficulties have been largely overcome by taking special care to get the crop in early, so that in normal years, at least, a fair growth of peas is obtained in time for ploughing in. But apparently orchardists generally are not prepared to take these special precautions. I think another reason why green manuring is not more used is, as shown by American experiments, that apple orchards on good soil may not show the effect of the gradual loss of humus till the trees are up to twenty years of age. When that point is reached, however, it takes many years to build up the fertility again, and restore the yields by means of green crops.

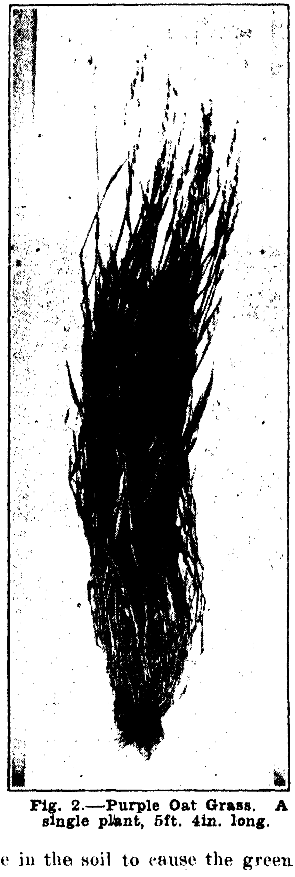

Fig. 2.—Purple Oat Grass. A single plant, 5ft. 4in. long.

Now the crop usually tried, and to which these difficulties specially apply, is peas. So the problem seems to be to get some substitute by means of which these difficulties can be overcome. I believe we have such a substitute in Purple Oat Grass (*Ehrharta longiflora*), an introduced annual from South Africa.

Of the three illustrations, Fig. I. shows the dense growth, most of the stems leaning over more or less; Fig. II., a single plant 5ft. 4in. from the root to the end of the flower heads; while Fig. III. shows two single heads, about half the natural size, much like oats in appearance, only smaller, and with a purple spot at the base of each flower. These photographs were taken in the spring of 1931.

This grass is very common in the suburbs of Adelaide, usually growing in gardens and along the fences in the streets. It is also found in many places in the Mount Lofty Ranges. Pastures do not seem to suit it, probably because grazing animals, being very fond of it, bite off the seed heads, which are borne high up on the stem. Thus it does not get a chance to reproduce itself. Where protected it seeds prolifically, and should be quite easy to reap, in much the same way as oats. Seed gathered from the crop illustrated gave the following results on germination:—

	Per cent. Germination.
Seed dry and ready to fall	52
Seed ripe, but still green	44

The plant is very hardy, growing well even on poor, sandy soil with a little phosphatic manure. Where growing thickly, it soon kills out most other herbaceous plants. Soursobs it will exterminate in two or three years, if encouraged by a little fertiliser, and the same probably applies to Sorrel. It stools well as shown in Fig. II., and forms a dense mass of growth as shown in Fig. I., giving a large amount of green matter. The piece of ground in Fig. I. was self sown, and grew nothing but a dense mass of soursobs two years previously.

And last, but not least, it shoots very early and ripens in plenty of time for ploughing in in the spring. This year (1932) it was 2ft. high, and beginning to flower in the middle of July, which allows considerable latitude for the earliness of the season.

Comparing it with peas, while it would return much more humus to the soil on account of the heavier crop of green stuff, it probably has not the power of abstracting nitrogen from the air as peas have, and would, therefore, only return what it took out of the soil. On this point, however, it has long been known that South Australian soils do not need nitrogenous fertilisers for most crops. This has been shown to be due to the action of the soil bacteria on the decaying humus. During the hot summer months, if the air is enabled to penetrate the soil through a loose surface mulch, they convert large amounts of atmospheric nitrogen into substances which can be used as plant foods. In experiments recently carried out at the Waite Institute, available nitrogen equal to 4cwts. of sulphate of ammonia per acre was produced in fallowed land each year. This should surely be sufficient for the requirements of most orchards, excepting citrus.

But it must be remembered that, for this process to go on, there must be a sufficient supply of humus. I understand that Sulphate of Ammonia has lately given payable results in experiments in South Australian orchards. But, in such cases, excepting, of course, with citrus trees, I think it will be found that the soil is deficient in humus, and, therefore, unable to fix atmospheric nitrogen. I am informed that in one such experiment the land has not had any green crops or stable manure ploughed in since it was first planted fifteen years ago.

It seems very probable then, that with phosphatic manures (and potash in deep, sandy soils) applied to a non-leguminous cover crop, no more fertilisers would be required for most South Australian orchards, excepting citrus. For citrus orchards this treatment would probably have to be supplemented with an extra dose of nitrogen, as sulphate of ammonia.

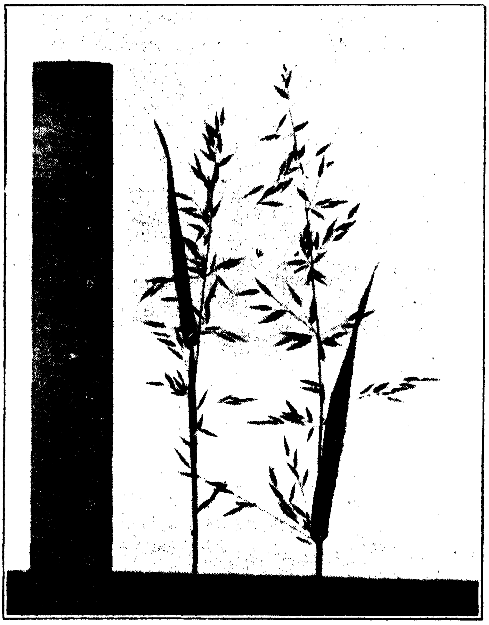

Fig. 3.—Purple Oat Grass. Two Flower Heads.

It appears, then, all things considered, that Purple Oat Grass would fill the bill as a green manure crop for South Australian orchards. Cultivation is easy. The seed would merely need to be drilled or broadcast and harrowed into the soil mulch early in the autumn, while it is still dry, thus ensuring an early start. It would then be ready for ploughing in in the early spring.

Unfortunately, there is not yet a supply of seed on the market, but we have a small quantity on hand in the Department, from which small samples can be distributed to orchardists, who can quickly increase it for themselves, while if there is any considerable demand a regular supply will, no doubt, soon be forthcoming from the seedsmen. Applications for seed should be directed to the Department of Agriculture, Horticultural Branch, Exhibition Building, Adelaide.

Finally, Purple Oat Grass should be worth trying as a hay or ensilage crop on land which is smothered with weeds. And it would surely give good results on pastures, if they could be managed so as to give it a chance to mature and drop its seed each year. The seed falls as soon as it is ripe, so it may be quite practicable. These two further uses are, however, matters for experiment.

LOWER NORTH PRUNING COMPETITIONS.

In the competitions for the Parsons Cup, which has been donated by Mr. W. Langdon Parsons for the competitor who gains the highest aggregate of points over three years ending in 1933 in the Lower North Local Pruning Competitions for both fruit trees and vines, the Secretary (Mr. J. S. Hammat) reports that Mr. B. Fromm (Lone Pine) was the successful competitor in 1931 and Mr. F. W. Boehm (Light's Pass) in 1932.

The following table shows the points gained by the competitors who secured more than 1,000 points during the past two years:—

Competitor.	Trees.	Vines.	Total.	Trees.	Vines.	Total.	Grand Total for Two Years.
F. W. Boehm ..	358	186	544	371	185½	556½	1,100½

PAPERS READ AT CONFERENCES.

THE BIRD PEST AND HOW IT AFFECTS FRUIT PRODUCTION.

[By Mr. F. W. ALLISON, Strathalbyn.]

(*Southern Conference, Belvidere, August 18th.*)

The subject of this paper is one which does not cause the general farmer very much concern, but when one considers the total amount of fruit grown and exported, and how it re-acts on the whole State, it is a subject that must command attention.

With each succeeding year, so mounts up the increase of birds and the cost of protecting the fruit. During the last six years I have been able to observe many of the difficulties under which the fruitgrower is laboring to protect himself against the ravages of the many kinds of fruit-eating birds. More especially is this noticeable on the smaller holdings which produce from 1 to 4 tons of currants, with stone and pip fruit proportionately.

The birds are great workers, working from daylight to dark. This means constant and tireless attention, which is an enormous tax on the grower of time, money, and patience. At the present time in the southern districts, no concentrated efforts are being carried out to combat this pest, it being purely on an individual scale, and further, while growers remain passive, nothing in the way of assistance will ever be accomplished.

By observation, it has been found that birds, in the following order, are those that are doing the damage. The starling, sparrow, silver-eye, parrot, and minah. Of these the starling is most destructive, and these birds will soon do extensive damage to the fruit if left alone for only a short time.

One can only conjecture at the amount of fruit taken when these birds swoop down on vines in flocks of 500 or 1,000 or more, even if they only take two or three berries each raid, this will soon mount up to large proportions, for this continues each day, from the time the fruit begins to color until it is picked. A vigneron of Langhorne's Creek estimates his loss at £50—for protecting and keeping the birds off—another at £40, while a very conservative figure for protection and loss of fruit in that locality is placed at £500. And what applies here also applies more or less to the whole State where fruit and almonds are grown.

Various means are used to combat the pest; mechanical devices of all shapes and designs have been tried, but with very little success, for the birds will very soon get so used to them that they will sit on or around them. The only successful method must come through the use of manual labor and by the continual use of the whip, the gun, or a kerosene tin. Yet all these methods are of a very temporary nature.

Something definite and of a concenterated organised nature must be done to be of any real value, and must be simultaneously carried out. Good results in isolated cases have been accomplished by scattering poisoned currants under the vines and trees immediately after the fruit has been picked; or by the formation of clubs to collect heads and eggs at so much per hundred on somewhat similar lines to those formed in parts of Victoria, and that the Government be approached to assist the fruitgrower on an equal basis.

Another point is the wholesale manner in which starlings and sparrows scatter the seed of boxthorn and other noxious weeds. Still further, that the class of birds dealt with in this paper are largely responsible for pushing out the smaller non-fruit eating kinds, such as wagtails, larks, wrens, swallows, and a number of other smaller ones. After giving this question serious consideration I am convinced that the caterpillars and grubs these various birds devour do not compensate for the amount of damage and loss of capital incurred by the fruitgrowers of the State, and that the time has arrived when concentrated effort must be organised to combat this pest.

THE DAIRY COW.

[By Mr. W. Robinson, Currency Creek.]

(*Southern Conference, Belvidere, August 18th.*)

Many farmers who have been chiefly occupied in the production of wheat have, owing to the falling prices in wheat, turned their attention to dairying, and have established fodder plots and installed milking machines on their premises. The chief reason is that cream invariably returns, regularly, ''ready cash,'' which in existing times is most essential, while wheat returns, owing to fluctuations, are so uncertain.

With all the natural possibilities and suitable land available in this district—which carries an abundance of natural grasses—there is a splendid opening for an enthusiastic farmer to establish a good dairy herd, commencing on a small scale with good sound stock, and with that end in view the following points may prove helpful to the prospective farmer in selecting a good type of cow as a nucleus for his herd.

Production Factors and Essential Characteristics of the Ideal Dairy Cow.

To be successful in dairying, a man must have many attributes, but above all he must be a good judge of the dairy cow. No one can hope to tell from the appearance of the cow how much butterfat she will yield. This has been demonstrated repeatedly ever since herd testing began. The only really reliable guides are the scales and the Babcock milk tester. Unfortunately, however, cows cannot always be purchased on their test record, and in purchasing new blood or building up a herd the dairyman who has a sound knowledge of the essential points of a dairy cow will make fewer mistakes than the man who has not the knowledge.

It must be borne in mind that to all intents and purposes the dairy cow is a "machine" for the reproduction of her kind, and for the production of milk and butterfat. Her commercial value depends on the quantity and quality of her production, and her ability to maintain her productiveness over extended periods. If the machine is to function properly and profitably certain characteristics are essential. Among these the most important are:—

1. Constitution;
2. Capacity;
3. Nervous Temperament;
4. Blood Circulation; and
5. Ability.

Each of these characteristics enumerated is so vitally important that it is difficult, if not impossible, to say which is most essential. Unless they arq all in proper development, profitable production cannot be expected. These essential characteristics are not confined to any particular breed of dairy cow more than another. The choice of a particular breed is only of secondary consideration and a matter of personal preference of the farmer. The important thing to ascertain is that the cows that are selected have the above characteristics.

If she is to produce a satisfactory quantity and quality of milk a cow must have capacity, and if she is to continue the good work throughout her lifetime she must have a vigorous constitution and abundant vitality.

Constitution in a cow is determined by several factors, foremost of which is ample breathing capacity. Oxygen is essential for the purification of the blood, and if the cow is to receive the required amount of air a large breathing capacity is required. This is demonstrated by a good lung capacity and large, open nostrils. If the nostrils are small and not well opened the amount of oxygen which reaches the blood through the lungs is restricted, and constitutional vigor is underdeveloped. Small nostrils are a definite indication of low breathing capacity.

The vitality of the animal is determined partly by the size and capacity of the chest, within which are located the heart and lungs. The dairy cow should be deep in proportion to her size, from the top of the shoulder to the base of the chest. To give the vital organs ample room for development and action, the foreribs should be well sprung, but not broadened out into the wide spread of the beef animal. Another indication of vitality is found in her eyes. Bright, clear, and prominent eyes are evidence of vigor, while the cow with dull, sunken eyes is usually the animal to be avoided.

By capacity is meant the total amount of food she can consume and digest, while her profitable capacity lies in the amount of food she can assimilate above the quantity required for her bodily maintenance. Usually cows which are big feeders are more profitable than those of a smaller capacity, for they are less dainty in their tastes, and will consume a greater proportion of the more plentiful and coarser roughage. Cows with limited capacity are more likely to go off their feed and get out of condition, with the result that the milk flow also falls away. A cow must be fed heavily if she in continually in milk.

A large mouth is a matter of prime importance. This feature indicates a good feeder, and the best evidence of capacity is a large barrel. This is accompanied generally by length of body with broad, deep, and well-sprung ribs, and a large girth measurement in proportion to the size of the animal.

Breadth and depth of body are more desirable than length. Lengthy bodies within the well-sprung ribs indicate generally a poor feeder, a poor producer, and a poor mother.

The condition of the hair and skin must next be taken into consideration. The cow with a hide that is soft and pliable, easily lifted from the body, and covered with a soft, silky coat of hair is in good condition, and has her digestive apparatus in proper working order. Dull eyes, harsh skin, and wiry coat, are indications of digestive troubles.

So far as the nervous temperament is concerned, a dairy cow should have a strongly developed nervous system to enable her to carry on with milk production and her offspring. The term "lymphatic temperament" is essential for beef cattle. These two temperaments are contrasts. The "lymphatic" enables the animal to lay on beef, whilst the nervous temperament enables the cow to lay on milk, *i.e.*, they may eat the same food but make different uses of it.

Nervous temperament is indicated by a long, broad forehead with plenty of space between the eyes. Other indications are prominent, large, and intelligent eyes. Freedom from beefiness, absence of surplus body fat, and extreme angularity of form, with prominent hip bones and ribs, are also evidence of the desired nervous temperament.

Blood circulation is next important. Unless the cow has a good circulatory system she cannot derive the maximum benefit from the food consumed. The milk veins which extend forward from the udder are actually blood veins, and their size, length, and form serve to determine the quantity of blood which flows through the udder. These veins terminate in the so-called milk wells which are the openings in the abdominal wall where the veins re-enter the body. Usually both the milk veins and the milk wells are large in heavy-producing cows. With large productions the veins may be also very crooked and have several branches with as many milk wells. Therefore, the development of the system of milk veins is one of the best indications of milk production capacity of the cow.

The fifth characteristic—the ability to produce—is not merely the capacity of the cow for milk production. She may have the capacity and yet lack the ability to produce up to that capacity. By capacity is meant that the cow can consume, digest, and make use of or assimilate large quantities of feed, while ability means that she can turn the nutriment elements of that food into milk and butterfat. It is, perhaps, the most important of all the characetrisics, for without it the others are of little avail.

The size, form, and texture of the udder are practically the only indications or outward manifestations of her ability. The udder should be long and broad, attached high behind and extend well forward. Its breadth should fill the space between the thighs, and it should have a nearly level bottom line parallel with the underline of the body. A deep, pendulous udder is not desirable. Quality and texture are highly important in the udder.

There is evidence of both when the vessel is soft and pliable, capable of great expansion when full, and equally great contraction when empty, and covered with a coat of silky hair. It should be well distended and smooth before milking, and should gradually collapse in numerous soft folds when the milk is withdrawn.

Though the foregoing are not infallible rules, a knoweldge of the essentials and characteristics outlined above are necessary for the dairy farmer who hopes to build up a first class herd. Used sensibly and in conjunction with testing, that knowledge should provide both profit and pleasure to the owner, for there are few occupations more interesting than the breeding of high class livestock, and particularly dairy cows.

THE DAIRYING INDUSTRY.

[By Mr. A. G. Ifould, Port Elliot.]

(*Southern Branches Conference, Belvidere, August 18th, 1932.*)

At the present time the dairying industry is playing a most important part in solving many problems regarding the man on the land, and it behoves every producer to assist the State in one of the worst financial depressions ever experienced, and the cow is going to help materially to improve matters. The foundation or building up the herd plays the most important part in successful dairying. First it is necessary to form the cow's udder. Judicious milking: milking the back quarters always first, throwing the milk into the front quarters, helping to balance the udder. This is the most important part of the dairying industry. It does not matter how well the cows are bred or their high testing ability, they can be utterly ruined in the first milking causing disabilities in the dstribution of the milk flow. Every dairyman knows that the cow's udder is a network of machinery, and that machine requires proper management and consistent milking, which can only be done by a life-long experience and careful manipulation. Kind treatment of the animals is essential. There are many obstacles to overcome, such as ailments, &c., one of the worst being mammitis, which by careful drying off and watching the symptoms, can be overcome, as in other troubles prevention is better than cure.

''Cleanliness is next to Godliness,'' and all produce connected with milk, cream, etc., should be delivered to factories in the most hygienic condition, then it will be possible to compete with the markets of the world.

POULTRY ON THE FARM.

[By Mr. C. Fairmann, Hartley.]

(*Southern Branches Conference, Belvidere, August 18th, 1932.*)

At the present time many farmers are keenly alert for any opportunity to introduce into their holdings new or extra sidelines. For those favorably inclined towards poultry, the following points may prove helpful in the selection, care, rearing, and feeding of their stock. As it would perhaps take quite a considerable time to get broody hens suitable for raising chickens, the purchasing of the foundation stock from a reliable poultry farm with a reputation for good birds is suggested.

The foremost consideration should be the type of bird most suitable to the locality and the particular ''fancy'' of the farmer. There are various types on the market, but the White Leghorn and Black Orpington appear to be the most popular breeds. Other breeds, such as Minorca, Plymouth Rock, Buff Orpington, Wyandotte, and Rhode Island Red also find favor with some breeders, but the two first-named are undoubtedly the most popular for egg production. The Black Orpington is perhaps the better of these two, owing to its size, for it may be used as a table bird if it fails in its mission of egg production.

In most cases it will prove more profitable to buy chickens and rear them on the farm, taking care to study the correct methods of feeding and housing the chickens.

Chicks need no feeding for the first 48 hours to 60 hours after hatching, as part of the yolk—approximately 1 cubic centimetre—goes into the stomach on hatching. When commencing the feeding, give crushed wheat, chaffed green, and water, plain bran or pollard, Mashes should not be given to young chicks; they are liable to cause bowel trouble, although buttermilk may be fed to advantage. Dust chicks freely with an insecticide to kill off any parasite while they are in the brooders.

Housing.

Having thus established a foundation for pure-bred stock, the next in importance is the housing of the young birds. Cleanliness and neatness are essential. Endeavor to build a house on modern lines. Housing prevents fowls from roving amongst haystacks, stables, and gardens, and they do much better when housed correctly. Make the conditions as roomy and as accessible as possible. The house should be built in the direction that will eliminate draughts and should not face the quarter from which the rough weather prevails. For this purpose a house facing the east or north-east is preferable, because birds appreciate warmth and sunlight. The back and sides can be constructed of galvanised iron and the front of netting and ordinary window glass or a glass fabric. Avoid wooden buildings if possible; these become harbors for parasites.

Ventilation is important. Plenty of fresh drinking water is of primary importance, and the best way of doing this is to have a dripping tap somewhere in or near the house where the bird can get fresh water at will. Concrete or bitumen makes the best flooring; it does not readily become damp. The house should be thoroughly cleaned at least once a week.

Litters—not mouldy straw or hay—should be spread on the floor for scratching purposes, and the grain when fed to the birds should be scattered among this litter, so that the fowl has to scratch for it, giving it extra exercise, which is necessary for the housed bird.

Perches, under which dropping boards are placed, should be 18in. to 2ft. high, and of convenient shape for the birds' feet to hold on comfortably. Wrongly constructed perches lead to deformities. Nests can very well be made of kerosene or petrol tins cut open on the end and about half filled with shell grit, with perhaps a few pieces of charcoal and finely cracked china added. Do not on any account use straw for nests.

FEEDING.

Feeding of the stock is another important factor in successful poultry-keeping. Remember that the hen is a laying machine and cannot continue to work without energy. Food creates energy, therefore birds should be fed correctly to get the eggs. It takes as much to feed one fowl as it does to feed another, hence the necessity to keep only the best strain of birds. Use only the best of foods and avoid the feeding of spices; they are useless in promoting egg production.

For egg production it is necessary to have large-framed birds; these invariably lay large eggs. For the purpose of building frame and shell in the bird, lime has been proved of considerable value. It is a good plan to place lime in the drinking water. In the absence of lime, powdered superphosphate or ground and burnt bones may be used to good effect. In any case, 1 saltspoonful of the above should be put into the birds' mash daily; it builds frame for the bird and adds lime for the shells in the laying strains.

Making a Mash.—The quantities taken are for one bird daily:—½oz. bran, 1oz. pollard, 1½ozs. chaffed greenfeed. Use 1½ozs. greenfeed for winter feeding, and 3ozs. for summer feeding. Lucerne, rape, or mustard make excellent greenfeed for the birds. Add to this wash about 10 per cent. of the dry constituents by weight of meat meal or rabbits or other meat.

The water used for mixing could be the drainings of waste household scraps boiled. In addition to the mash, feed grain as follows:—2ozs. daily for layers and 1½ozs. for non-layers during the day. Mashes should be fed either night or morning as is convenient, although night feeding is not as preferable as morning. If mash is fed in the morning, grain could be given to advantage at night.

The seasonal effects of birds must be closely watched, because they go into a moult during autumn. It is advisable, therefore, to get chickens six months old in March. March hatched chicks come in in September and lay while the others are moulting.

The egg market at present is not very encouraging for inferior eggs, but we should endeavor to compete with the overseas markets, for which prices are favorable. At present we are exporting something like 100,000 cases per year overseas, and there is no reason why we should not be exporting half a million cases. We should see that the standard and quality of the egg sent overseas is good and of standard weight, which should be from 1¾ozs. to 2¼ozs. It should be the aim of every poultrykeeper to see that he keeps a class of bird that lays eggs of 2ozs. or more in weight, and 300 eggs under 2ozs. are not as good as 200 over 2ozs. It will readily be seen that only good quality stock should be kept, and any bird that does not lay large-sized eggs and about 220 per year should not be used for breeding purposes.

A hen is commercially useful up to 3 years, and after that should be culled from the flock. The hen is, in reality, a laying machine, and as with all machinery, cannot go on working for ever, so it will become necessary for the keepers to maintain the standard of their strain by culling out old birds periodically.

When culling, it is advisable to cut out any deformed, sick, or diseased birds, for one fowl may cause the destruction of the whole flock through diseases, &c. As the flock diminishes through periodic culling, it will be necessary to breed more chicks to keep up the desired number of hens, and a few hints here on the selection of eggs for hatching may prove beneficial to the beginner.

All eggs selected for hatching purposes should be from 2ozs. to 2¼ozs. in weight; anything over that weight is not recommended. Select smooth-shelled eggs, free from any wrinkles, and avoid any abnormal eggs. Two shapes that are considered good are the long shape of the White Leghorn and the round shape of the Black Orphington. Avoid misshapen eggs and also those with rings around them. If they are dirty before setting, wiping them with a damp cloth will not be harmful. If setting under a broody hen, see that the hen is freely dusted with an insecticide to kill off any parasites, such as mites, lice, &c.

The eggs should be set on slightly damp ground, because they need warmth and moisture to germinate efficiently. Do not, on any account, use straw; it forms a home for the breeding of parasites.

If an incubator is used, use a reliable make and attend to the directions given by the makers. After the experience gained in laying the foundation of a good laying strain of birds, poultry-keeping should present very few difficulties and prove interesting and profitable to the farmer who takes it up as a sideline.

THE PROBLEM OF MAKING FARMING PAY IN THE MALLEE AREAS.

[By H. SANDERS, Yurgo.]

(*Murray Lands, Karoonda, August 2nd,* 1932.)

Having been in this district just 21 years, the writer can claim to know something of the subject of this paper. The following remarks or criticisms are not made in any carping or disgruntled spirit, but with a desire to assist, if possible, some of the farmers in the Mallee who have not had so much experience nor the opportunities for learning.

It seems likely that for some years at least primary producers cannot expect to receive more than comparatively low prices for their products. The first job is to set about reducing costs of production in every possible way, and the man that can balance his budget each year will be in the best position to take advantage of any improvement when it comes.

There are several ways in which costs can be reduced: improved methods of working fallows and seeding; using the most suitable varieties of wheat and oats; careful study of the most suitable rotation for the district; using the most economical quantity of manure and the right sort of manure; the most suitable sidelines; and, finally, to market the farm products in such a way that the best return will be obtained.

IMPROVED METHODS OF WORKING FALLOWS.

This question is worthy of a paper to itself. Travelling about the district, one often notices that the farm operations are being conducted in anything but a satisfactory manner. Bad farming undoubtedly injures the credit of the district and all those that live in it, and where such practices are continued until they bring about the ruin of the farmers, who, in many cases, have received Government assistance, all have to contribute indirectly through taxation. Waste, whether it be of time, energy, or money, has to be paid for, and there is no dodging it. One often sees a farmer using an unsuitable implement, or one in bad order or too large for the power available. This results in a poor job being made of the first ploughing. It is impossible to make a good fallow after a poor start, without a lot of unnecessary work. Deep ploughing is not necessary in this district, but it must be deep enough to insure that all the ground is moved, and, if possible, turned right over and afterwards worked when necessary. The same applies at seeding; see that each implement is in a condition to do the work for which it is intended.

USING THE MOST SUITABLE VARIETIES.

There are many varieties of wheat and oats which have been well tested, and the wheat that will be best for one farm may not be so suitable for another. However, there are several varieties of early and mid-season wheats which stand out from others, and there is ample scope for individual choice. No one wheat will come out on top every year, and it is always advisable to sow at least four varieties and escape as much as possible the ravages of droughts, frosts, rust, takeall, and other handicaps. Whatever varieties are selected, see that they are free from barley or oats, properly graded to eliminate cracked or shrivelled grains and efficiently pickled, and a better crop will result, with a corresponding decrease in the cost of producing.

MOST SUITABLE ROTATION.

From the Crop Competitions it appears that a four-course rotation is the most favored in this district. Bare fallow, wheat, oats—either for grazing or grain—pasture, appears the best rotation at present, but as the country becomes older it may find it advisable to alter the foregoing somewhat on the following lines:—fallow, wheat, oats sown with lucerne, pasture, pasture, pasture. I have sown over 100 acres with lucerne this year, and intend to continue each year so far as circumstances will permit.

FERTILISER DRESSINGS.

This is an important question, and in the light of experiments conducted by the Department of Agriculture on my own farm over a period of nine years of varying seasons, 2cwts. per acre of 36 per cent. superphosphate proved the best proposition. It has given the best yields, and the residual effects on the pasture in after years is most marked. I am aware that it takes courage as well as finance to use 2cwts. of manure, and it is realised that no quantity of manure will grow a crop if the land is not suitably worked to receive it; but my advice is, if the fallow is good put the maximum amount of manure into it. Results of experiments over the last two years with sulphate of ammonia on stubble land have been astonishing. Last season the plot which was dressed with 1cwt. 45 per cent. super. yielded 8cwts. 103lbs. of hay; 1cwt. super., ½cwt. sulphate of ammonia, 14cwts. 30lbs.; 1cwt. super., 1cwt. sulphate of ammonia, 21cwts. 88lbs. per acre. As this manure is expensive, one hesitates to advocate its general use, but wheat sown on stubble this year promises to show even bigger differences than last year's.

SUITABLE SIDELINES.

Without a doubt, sheep come first under this heading, and I am firmly convinced that, other things being equal, the man that runs sheep will grow at least a bag to the acre more than the man who does not. Here is one instance where the protective tariffs hit the producers very hard: Australian or New South Wales wire costs £18 per ton, and if it were not for the embargo English wire landed at Port Adelaide could be bought for £11 and Continental wire for less.

Much prominence has been given to dairy cows on the farm, and it is agreed that where a man has suitable labor and feed, they have their advantages, but in many cases they do more harm than good. Men who have not the time, the fencing, or the feed, are running a few cows—often of a poor type—which are a constant worry by getting into the crops. They are taking up the time of the farmer which should be employed in working the land and producing a payable crop, but for the sake of the ready cash the farm work is neglected, and at harvest time the results are poor.

POULTRY AS A PAYABLE SIDELINE.

[By S. EYLES, Clarendon.]

(*Hills Conference, Clarendon, August 25th,* 1932.)

This paper is my opinion of what one should do to make the most out of poultry as a sideline. There are three main points to consider, first, strain and breed; second, housing; and third, feeding.

First procure a good strain that will lay a large egg. Buy settings or chicks from a reputable breeder. Generally speaking, the heavy breeds such as Black Orpingtons lay better than the light breeds in winter and will stand much more rough usage, but eggs can be obtained from strains of White Leghorns that will lay all the year round if properly cared for. The average farm fowl is usually a mixture of breeds and lays eggs when they are cheap—they put in about four months of the year going on and off broody—and in my opinion are not worth their keep. I had about 300 birds of a well-known strain and collected 1,811 eggs in four months from April to July; I cleared this lot out and purchased the strain I have now, and in the same period I collected 3,870 eggs from about 100 birds. More than twice as many eggs at about a third the cost of feed.

HOUSING.

The birds will not lay in the winter unless they are kept warm, dry, and busy. The best thing to do is to provide a shed, where the birds can be closed in. If it is proposed to start with 100 layers a shed that will accommodate 150 will be needed, because 50 old birds should be culled out each year. One compartment each for the second year hens, one for first year hens, and one for pullets coming on to lay. A shed 30ft. long by 16ft. deep, divided into three, will suffice because each bird requires 3ft. super floor space. The second year hens should be sold when they go off laying in the autumn. There is usually enough wire netting around hay stacks, vegetable gardens and flower gardens to make a yard to keep the fowls in when they are let out of the house in fine weather. This should be done, because, if allowed to roam anywhere they do a lot of damage on a farm and soil the trollies, implements, &c., by roosting on them. If the birds are kept from roaming the eggs will always be laid where they can be gathered without a ladder. Have a yard about a chain square, with the fowl house in the centre. If the yard is divided into smaller yards, these can be cropped with barley, rape, kale, mustard, &c. A patch of lucerne is the best for summer feed. It will pay to feed as much greenfeed as the birds will eat, this will save bran and pollard, and will produce more eggs and better colored yolks.

The house should face north or north-east, but do not face a gully wind. The yards should have a slope to facilitate drainage. Provide a cement floor in the house, if not all over at least under the perches.

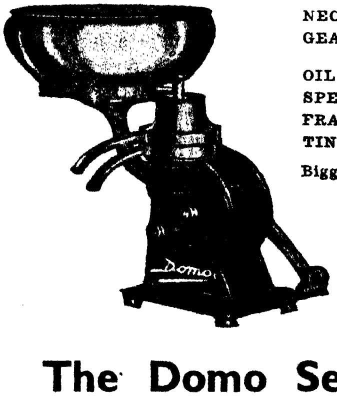
Perches should be fixed in the most sheltered place, allowing 9in. perch room for each bird, and have all the perches on one level; about 18in. from the floor. The best perch is made as follows:—Drive a piece of water pipe 30in. to 36in. long into the ground until there is about 17in. left above ground; one at each end of each perch; get a hardwood perch, about 2½in. to 3in. wide by 1¼in. to 1½in. thick, bore ⅜in. holes at each end about 6in. from the end, to correspond with the holes in the pipe, drive a 6in. x ⅜in. bolt through the hole in the perch into the pipe. These perches are easily removed to clean out underneath and to oil, which should be done every two weeks during summer to keep down red mite. Nine or 10 nest boxes will be required in each pen. These should be off the ground—kerosene tins make good nests. Make a cut 2½in. up on one end and remove the large piece of end, have a perch in front of the next boxes about 9in. away from them. Have the tins about 18in. above the floor to save floor space. Dry mash hoppers will also be needed. These can be made at home or purchased ready made. They should also be kept off the floor. If the shed is floored with cement or bitumen, provide a dust bath as follows:—Nail two pieces of wood about 9in. wide by 4ft. long to form a right angle, and fix in one corner of the pen, about half fill with sand, road grit, or similar material, and mix in some wood ash, and if you have any flowers of sulphur, about three or four handfuls will be an improvement. Sieve this dirt occasionally and see that the same quantity is maintained. Have a slab or board about 9in. wide in front of perches to keep the scratching litter away from the manure under the perches.

Arrange a place to keep the water tin where the sun will not shine on it. This also is better when placed above the floor level, and provide a tin large enough to hold a full day's supply. See that the house is high enough to permit of walking without

THE NEW MODEL DOMO

AWARDED THREE PRIZES AT THE ROYAL SHOW, ADELAIDE, 1932

ARRIVED ! !



SKIMMING BOWL, semigyroscopic.
BOWL SPINDLE, with improved conveyor.
NECK BEARING, with spiral spring cushion.
GEARING, new Automatic type. No springs or pins to handle.
OIL SUMP protected against milk or water.
SPEED INDICATOR.
FRAME beautifully enamelled, and
TINWARE heavily tinned.

Bigger sizes fitted with BALL-BEARING SPINDLE, eliminating neck bearing and reducing OILING TO ONCE A YEAR.

Write us for our Easy Terms and Allowance on old Separators.

30 DAYS' FREE TRIAL WILL ENABLE YOU TO TEST IT IN YOUR OWN DAIRY.

The Domo Separator Company
OFF WAYMOUTH STREET (Opposite "Advertiser")

stooping. Pea straw about 6in. deep makes a good scratching litter; old, dry stable manure is also good. Only a very small quantity of scratching litter is needed in the hot months because then the birds do not want too much exercise. Have ¾in. wire netting on any openings in fowl house to keep out sparrows.

Arrange a trap door to each pen about 6in. above the floor level. The floor of the house should be about 6in. higher than the outside ground level to prevent flooding. Make the house as nearly draught proof as possible, with ventilation at the top.

FEEDING.

The easiest and most convenient way to feed fowls, whether they are shut in or not, is the dry mash system. Dry mash costs no more and the egg yield is very little below the wet mash in the various competitions. Another point is that it does not sour like the wet mash if not eaten up quickly.

The mash I use is as follows:—60lbs. pollard, 30lbs. bran, 10lbs. meat meal, add not more than half a tea cup of table salt to the meat meal before mixing with the pollard and bran. See that there are no lumps of salt, and thoroughly mix all together. This quantity should be enough to last 150 fowls about six days with the addition of 2ozs. of wheat per bird per day, and as much greenfeed as they will eat. When the birds are in full lay add 15 per cent. to 20 per cent. more bran and reduce the meat meal by 3lbs. to the amount of mixture given. In hot weather, the addition of 25 per cent. of lucerne chaff or, failing that, 10 per cent. of lucerne dust, will be appreciated by the birds. Fowls will not gorge themselves on dry mash, they cannot eat a lot until they have moistened it in their mouths as an aid to digestion.

When greenfeed is available give a feed of chaffed material at midday—about one kerosene bucket to 150 fowls—and another feed after they have had wheat at night. If the green feed is not chaffed grow rape, mustard, chou mollier, or cabbage. Give the leaves tied up in bunches and hang them up so the birds can strip them. A fowl will consume about 45lbs. of wheat, 40lbs. of dry mash, and about 20lbs. to 25lbs. of fresh green feed, so that the cost of keep for one hen is approximately 6s. per annum. Wheat at 3s. 6d., pollard 1s. 3d., bran 1s. 2d. per bird, meat meal at 3d. per lb., this does not include cost of greenfeed. Cheap lines of wheat should not be used because they contain a large proportion of rubbish. A fowl has to lay at least 100 eggs each year to pay for its keep.

The average number of eggs laid per hen in South Australia is only 120, and as the commercial man cannot make a living under 170-180 eggs per bird it is evident that the farm yard hen brings down the average. If one obtains a good strain of layers of large eggs and takes the trouble to properly house and feed them it is possible to get an average of 170 to 180 eggs per bird or more if the boarders are culled out.

Two breeds—Orpingtons and Leghorns—are recommended for the man on the land. The Orpingtons will "go broody" and maintain supplies. With two breeding pens they can be kept mated as long as desired. The eggs not wanted for hatching can be used in the house. Select the best pullets and put a colored ring on them, then they can be picked out at any time. If a bird should go off color or "go broody" mark it with a different colored ring, and do not breed from any "broodies" or birds that have been ill. Dispose of these birds when you sell the second year hens. If there are 50 or more good layers it will pay to join an association to get top price for eggs.

If there are birds in the flock that are not earning their keep all the year, cut the losses, save a few to keep the house going, and with the cash from sale of birds it should be possible to purchase good settings of large eggs, not under 2ozs. in weight. To commence, it may be possible to convert a shed not in use. Make a yard and get some greenfeed planted. When a strain that is giving satisfaction has been selected, stick to it and when fresh blood is required go to the same man for it.

Oil the perches often in hot weather with kerosene and old engine oil mixed in equal parts. Look out for internal worms during September and October. The signs are dark tips to comb, with droppings frothy and yellow. If skim milk is on hand the fowls like it when they get used to it, but it should be fed in a vessel that can be cleaned easily.

Keep an account of all eggs laid, and when balancing the profit and loss account do not forget to charge the difference in eggs sold and eggs collected, also any fowls used for the table. There is another item that should be credited to the fowls' account—the manure. About 1½ kerosene buckets will be collected from under the perches of 50 fowls each week. If this is dried and sieved it can be used in the drill for top-dressing grass land. It is a very suitable manure for all vegetabes and worth at least 4d. per bucket.

BENEFITS OF IRRIGATION ON APPLE TREES.

[By R. Morphett, Clarendon.]

(*Hills Conference, Clarendon, August 25th, 1932.*)

My property is only in the early stages so far as irrigation goes, but results have been good. While the orchard was young there was no need for it, but as the trees got older it was impossible to get the fruit to size, even with thinning. It was also found that trees—which in their younger stages carried a crop every year—would only crop alternate years as they grew older.

In the season 1927-28—a good apple year—I had a very heavy crop and was unable to bring them up to size, although I thinned out. I finished the season after packing 200 cases of 2in., with about 700 cases too small for export, which meant that instead of a return of 5s. they realised only 1s. 3d., and a third of them were wasted altogether.

The following season, 1928-29, after such a gruelling, the trees did not produce a case of apples. I then decided to instal an irrigation plant to assist the trees in maturing their buds. The plant was installed in the 1929-30 season, which was a very disappointing apple season throughout the State, and finding that the apples were not filling too well I decided to irrigate. Irrigating was started early in January, 1930, but having heard so many different opinions on the amount of water per tree, I was frightened to give them more than 100 gallons per tree; finding three weeks later that the trees were not responding to the water I watered again, this time giving 200 gallons per tree, this seemed to have some effect, because I was able to pick two-thirds of the crop without further water. The other third of the trees which had a very heavy crop and from which I had picked a third of the crop was again watered about the end of February, giving 200 gallons per tree. I was then able to pick all of the crop for export, with the exception of about 40 cases. As the seasons were still keeping very dry, that yield compared favorably with the previous heavy cropping season, also the trees held the foliage very late and made good growth.

Having watered late that season and having 1¼in. rain soon after picking, I did not water to force the buds, but the following ''off'' season—1930-31—the trees averaged approximately one case to the tree, a vast difference to the previous ''off'' year, when I did not pick a case in the whole orchard.

THINKING AHEAD

The right kind of thinking ahead, of planning for the future, is that which is instantly translated into action, when the thinker, the planner, has decided upon the objective and the means by which it may be obtained.

Every man or woman who so plans must take money into consideration, and every man or woman who thinks must realise how valuable a means the Savings Bank account can be.

It costs nothing, cannot be overworked, and pays an interest profit commensurate with your tenacity of purpose.

Commonwealth Savings Bank of Australia

(E. C. RIDDLE, Governor).

As soon as I picked the apples in 1931, the orchard was ploughed and planted with Dun peas with as much super as could be got through the drill. They were about 4ft. high and flowering when ploughed in. As the season advanced the trees blossomed splendidly and a very heavy crop set. A week before Christmas I started to thin out and a week after started to irrigate, this time not taking advice from anyone. I have just finished and averaged 450-500 gallons per tree. Of course, I realise that water alone will not give satisfactory results, but with irrigation it is possible to manure, and this year I have had one of the most successful seasons on record.

MY EXPERIENCE OF FODDERS IN THIS PART OF THE MALLEE.

[By C. L. BRUCE, Nunkeri.]

(*Karoonda Conference, August 2nd,* 1932.)

Having realised in 1912 that this mallee country when first cleared grows very poor feed—mainly Yellow Daisy Bush and Long Rooted Catsear—and that it was essential to plant other grasses, from the commencement in 1912, I have sown the following grasses:—Madrid Brome Grass, Hairy Brome Grass, Barley Grass, Evening Primrose, King Island Melilot, Multi-seeded Millett, Subterranean Clover, Burr Clover, Cluster Clover, Woolly Clover, Haresfoot Clover, Perrennial Rye Grass, and Wimmera Rye Grass. In 1912 I scattered grasses which did well around our suburban garden, afterwards finding them to be Madrid Brome Grass, Hairy Brome Grass, and Barley Grass. Of these, Hairy Brome Grass and Barley Grass did fairly well. But as time went on I realised that I had made a mistake in so doing. Madrid Brome Grass proved a poor doer, very poor feeding value, and the stock only ate it when it was young. Hairy Brome Grass did well, but the stock only ate it when young, it was also poor feed, and the seeds became very troublesome in the mouths of the stock and in the bags of cereal grain. Barley Grass grew well and was a little better feed than the others, but the places where it was first sown in a few years proved the worst patches of the take-all.

EVENING PRIMROSE.

In 1915 a considerable quantity of Evening Primrose was sown. This did very well, grew a lot of feed, and harbored none of the cereal diseases. It proved a fairly good fodder, but as the sheep flock increased they did not allow it to seed in sufficient quantities to grow any quantity of feed.

SUBTERRANEAN CLOVER AND PERENNIAL RYE GRASS.

These were sown in 1922. Perennial Rye Grass did not seed itself in sufficient quantities to make a pasture. But for two or three years Subterranean Clover grew to perfection, having two late springs consecutively. At first it appeared that it would be a boon to the Mallee, because where the Clover was top-dressed with 2cwts. of superphosphate the plants choked out all other grasses and made a thick mat about a foot high, and next year the whole of the crop was sown with this plant. Unfortunately am early summer was experienced, and the Clover did not re-seed itself, and to-day, where it grew so well, there is not a plant to be found.

KING ISLAND MELILOT AND MULTI-SEEDED MILLET.

About the same time King Island Melilot was sown, but this has not grown very well, and its planting cannot be recommended, as the plant taints the milk and is detrimental to cream when sending it away. Another plant which grows well around the garden, Multi-Seeded Millet, was next transplanted around the fences of the paddocks, but this plant would not stand heavy feeding off and soon died.

BURR, CLUSTER, WOOLLY, AND HARE'S FOOT CLOVERS.

These were next sown in small quantities through the drill in 1925, and of these Cluster, Woolly, and Burr are doing well and are now established on the whole of my farm. The planting of Hare's Foot Clover proved a mistake because the growth it makes does not warrant the trouble of sowing it.

WIMMERA RYE GRASS.

In 1928 I planted Wimmera Rye Grass at the rate of about 1lb. of seed per acre; sown through the drill with the crop it has made wonderful growth, and is easily the best grass I have sown. Together with Mr. Griffiths and Mr. Garrett, Government Plant Pathologist, Waite Research Institute, we have searched extensively in the diseased parts of wheat and oat crops, and at no time have we found the Wimmera or the Clover plants a host for any of the fungus diseases. I now have the whole of my farm sown with Wimmera Rye Grass, and the carrying capacity is greatly increased. To-day I have 800 sheep mostly reared on the farm. It yet remains to be seen whether Wimmera Rye will interfere with the growing of wheat; it certainly entails more working of the fallows, and this should prove a benefit so long as one does not attempt to crop more than he has strength to work properly, particularly after the autumn rains, as all the seeds do not germinate with the first rains. To grow feed it is best to work the farm on a four-years' rotation—fallow-wheat-oats-pasture—sowing 1cwt. of superphosphate with the wheat and about 90lbs. on the oats, and then leaving the ground for feed the following year. It is best not to work the fallow in the spring, the light sandy soil drifts badly, and in so doing the seeds are destroyed and blown away. But with keeping sufficient sheep on the fallow to keep it reasonably bare of weeds, I have a pasture consisting of Cape Weed (Dandelion), Cluster, Woolly, and Burr Clovers, and Wimmera Rye Grass. The Cape Weed grows well with the first autumn rains and is a good milk producing feed while it lasts. With the coming of spring the Clovers and the Wimmera Rye Grass grew best, and undoubtedly are the best grasses from then until the next autumn rains. The stock do well on them even after they have matured; neither shed their seeds readily. The stock eat these seeds and so long as they have plenty of water do well on them through the summer.

THE ORIGIN, OBJECTIVE, AND RESULTS OF THE LAMEROO HORSE BREEDING SOCIETY.

[By W. MORCOM, Lameroo.]

(*Pinnaroo Line Conference, Jabuk, August 4th, 1932.*)

In August, 1928, at the Conference held at Pinnaroo, I read a paper entitled "Horse Breeding," in which I pointed out the necessity for breeding some foals every year to maintain the strength of the teams on the farm. In 1928 many farmers were using tractors and held the opinion that horse-teams were out of date. In the criticism that followed it was stated that more money could be made by keeping and feeding sheep than by feeding young horses. One Pinnaroo farmer asked me if I did not think we were out of date by not using tractors. The contents of that paper appeared later in a "Stock Journal," and came under the notice of a breeder of stud horses, Mr. A. J. Melrose, of Mintaro, who is a breeder of Percherons.

Mr. Melrose wrote me and offered to lease one of his stallions, stating also that he was anxious to get the Percheron horse into different parts of the State. He claimed that the half-bred Percheron was a very useful type of horse for farm work. That letter was received by me about the last week in August. At that time I was not in a position to handle a proposition such as was put to me, single-handed, but I thought the idea quite good, so I approached other members of our Bureau, who were also in favor of the scheme, with the result that before the end of that week we had held a meeting, formed ourselves into "The Lameroo Horse Breeding Society," secured stable accommodation, advertised for a groom, and by September 7th we had finalised all arrangements and the horse was at Lameroo. Of course news travels, and all the district knew that the Lameroo Bureau members had formed a horse breeding society and that a stallion was to arrive at a certain date, and much curiosity was aroused, especially as it was several years since any horse breeding had been done in our district. There is one satisfaction that I have in writing this paper to-day, and that is the fact that those farmers in our district who ridiculed what we had done and would have nothing to do with the horse that we were going to use are the sorriest men to-day. In fact one of our most severe critics, who said at the time that such a horse as that should never have come into our district, admitted to me six months ago, when he saw a pair of 2½-year old colts that I was working, that in another year they would be worth £60, and another said he wished he had a dozen of them.

The first year of our venture the horse was leased to us by Mr. Melrose for £40 for that season, and we had a very fair season, serving 47 mares; at the end of the season Mr. Melrose was very anxious that we should purchase the horse for which he wanted £100. After some consideration we decided that we would purchase same, Mr. Melrose agreeing to allow the £40 of lease money to go towards the purchase. We did not go into this business just to see what we could make out of other people, but for our own benefit, and we are prepared at any time to meet any farmer who is outside of our Society if he desires to make use of our horse. Of course, there is a certain amount of expense during the season when the horse is on his round, but during the remainder of the year one member of our Society keeps the horse and works him for his feed.

To show that our scheme has been a success, at the end of October, 1929, after the second season, having purchased the horse and paid about £120 in groom's wages and insurance, we had a credit balance of £57 4s. Since then the horse has not travelled the district, but has been used for members of the Society, and if any other farmers desire the use of same they come to us. In the Lameroo district those young horses will be seen in many of the teams, and they are good workers, quiet and docile, and there is no difficulty in picking them out because they have all turned after the horse for color, which is grey, which was one of the main objections that many people had to the horse.

Now that the horse has come into his own and, I am sure, is likely to remain for a good many years, members of the Agricultural Bureau cannot do better than follow our example and form Horse Breeding Societies—even if you only have 10 members. Buy your horse from reliable breeders, it will be well looked after and better results will be obtained, which has been the experience of our Society. We started our Society four years ago, we have had good success, and we are still going on, and I am pleased to be able to tell the Conference to-day that we are at the present time—although times and prices have been very much against us—in possession of some of the best Clydesdale blood in this State in the form of a two year old colt, and we also have a small credit balance in the bank.

THE DEVELOPMENT OF A HOLDING IN THE HILLS DISTRICT.

[By J. C. Blakely, Scott's Bottom.]

(*Hills Conference, Clarendon, August 25th,* 1932.)

When selecting a property note its natural potentialities, because it is from these that one will eventually plan out the working of the holding. Before arriving at the purchase value one must have a plan of subsequent action before him, also what it is intended to produce and the market value of same.

Clearing should receive first attention, cutting trees at a convenient height to suit the axeman. I do not advocate grubbing trees because the time taken is too valuable for the beginner to lose. I prefer treating the stumps with saltpetre and burning out. The timber should be cut in saleable lengths and stacked, heaping all boughs and rubbish for burning. The heaping of boughs should be done from day to day to prevent further souring of the ground by the tannic acid from falling leaves, &c. Good, shady trees should be left for summer shade, and patches of thick shelter for stock protection in the winter months and at night.

Trees suitable for cutting strainer posts—preferably pink gums—should be sawn in 6ft. 6in. lengths, leaving on the bark until strainers are required. Trees suitable for splitting fence posts should be cut in 5ft. 10in. lengths and split before they dry right out.

FENCING.

If no stock are kept do not worry about fencing until the land is grassed. If cows or sheep are to be kept, it will pay to wirenet because rabbits will soon appreciate your efforts in providing good feed. Place the posts 8ft. apart, 2ft. in ground, 3ft. 10in. out; strainers 2ft. 6in. in ground, 4ft. out; if you do not want to be coming back on your job every week, put up a good fence.

PASTURE.

Scarify the ground between stumps after the first autumn rains. A good, strong, cheap, and handy tool can be made; get a fork of a gum tree about 10in. thick and 4ft. long, such as would be used for a sledge, procure three steel spikes 18in. long by 1in., well pointed, and drill holes to take spikes. Place large cotter pins through ⅜in. holes in the spikes, with washers top and bottom. This tool if drawn over the ground will disturb the surface sufficiently for the reception of Subterranean Clover and Rye Grass. Top dress with 1¾cwts. of 45 per cent. super per acre. If sufficient cash is not available to buy super and seed, do not put in seed, but sow as much super as possible at the rate of 1¾cwts. to the acre, then fence and buy the stock. Do not over-stock, neither stock the holding unprofitably.

Subterranean Clover, Rye Grass, and Kikuyu Grass are best suited for the hillsides. The writer has established Subterranean Clover in the following ways:—Broadcast over ground after scarifying. Broadcast over dirty ground amongst rotted leaves, twigs, etc. Broadcast over oat crop after oats were drilled and harrowed in. Kikuyu Grass—transplanted slips. Rye Grass (English)—transplanted tussocks. The last two respond to every shower of rain in summer, Subterranean Clover leaves the ground bare in hot weather.

HAY.

Meadow hay cut on the green side and well cured should be carefully stored away, together with all other available dry fodder, because it will be very useful in winter. I do not advocate outside stacks, because the rainfall in the hills is too heavy for good preservation.

SUMMER FODDER.

Prepare the best flats by clearing tussocks and draining off surplus water. For a start do not spare the time to put down underground drains, they are expensive and the work must be done carefully to be effective, but put in a main drain to take care of floods. For this district Maize, Millet, Sorghum, Sudan Grass, Barley, Crimson Clover, White Dutch Clover, and Kale will respond well to irrigation. Lucerne, although giving little return the first year must not be overlooked. For a permanent pasture on the flats nothing can beat *Phalaris tuberosa.*

WATER.

A supply of water sufficient for stock and irrigation is an essential. Take advantage of Nature where possible in the reticulation of water; the cheapest method of supply is by gravitation or hydraulic ram if there is a running stream. In any case water will

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

TELEPHONE: CENTRAL 4855 and 4856.

nearly always be worth pumping. Overhead watering is more economical and beneficial to plant life than flooding.

PIGS.

Pigs should only be kept to consume waste, because, at present, market prices are below cost of production if food has to be bought.

POULTRY.

At first avoid large numbers, only keeping sufficient for home use.

GARDENING.

Although considered a precarious calling and very often responsible for great losses in cash and labor, gardening should not be overlooked by the beginner owing to the fact that it gives the quickest return. A strawberry patch offers fairly quick returns at little cost and light cartage for the man of small means.

ORCHARD.

Horticultural activities should not be mixed with grazing as a business, it should be gone into on a large scale or left alone, apart from a few mixed apples, pears, plums, and orange and lemon trees for home use.

Half the battle is to treat the farm as a hobby and select that line which makes most appeal. Have an ideal and live and work for it, and endeavor, when established, to produce as much for home use as time will permit. Much time will be saved by planning the work, but do not forget to work to a plan. The most experienced have disappointments, therefore it is evident that the beginner will have his share, more particularly if he knows everything on starting and has not sufficient time to join a Branch of the Agricultural Bureau.

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR SEPTEMBER.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

The work in the orchard during the next two months is such as will make or mar the crop. We could not have had better weather for the soil, but it was also good for the development of fungous pests, so that our spray programme must be very thorough, and no effort spared to get best results. Bordeaux Mixture and Lime Sulphur will be in evidence at once, and later on Arsenate of Lead.

Everything points to a good crop of apples again, and we must try to ensure that nothing prevents the trees from yielding their best. Consult the Instructor in your district if you are in any doubt what to do, but make sure that all the necessary implements are in good order ready for work, so that no delays occur.

Vines should be treated for Oidium, and see that Downy Mildew does not get a start. Try and take some of the vines off the trellis wires especially where they are becoming constricted; many hundreds of vines were badly damaged on account of this constriction; and further see that the cincturing is properly done. Vines are severely checked by deep cutting; all that is required is a cut through the bark only.

Finish grafting early, and use only wood from trees which are known to be good and of correct type.

The work of cultivating will, of course, have been finished, and all that is necessary is to keep a fine surface. Use the hoe to get all weeds away from the butts of trees. See that surface drains are open in case of floods.

Citrus trees may be planted if you will be able to water them later on. The young trees should be fumigated before being taken into the orchard.

Order new cases in good time and boil all old ones before taking them into the orchard.

If the packing-shed can be closed for a while a good catch of Codlin may be made at windows.

Aphis will be found on peach and plum trees and must be checked as soon as noticed. Black leaf 40, wet or dry, is the best remedy.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE AT CLARENDON.

Branches of the Agricultural Bureau situated in the Hills District met in Conference at Clarendon on Thursday, August 25th. There was a large attendance of delegates from the Clarendon, Longwood, Kangarilla, Balhannah, Blackwood, McLaren Flat, Scott's Bottom, Cherry Gardens, and Lenswood Branches.

Messrs. H. N. Wicks (Chairman, Advisory Board of Agriculture), W. J. Spafford (Deputy Director), C. F. Anderson (Poultry Expert), C. H. Beaumont, R. Hill, H. J. Apps (District Instructors), H. B. Barlow (Chief Dairy Instructor), R. Fowler (Manager, Blackwood Experimental Orchard), and H. C. Pritchard (General Secretary), attended on behalf of the Department of Agriculture.

Mr. J. Potter (Clarendon) presided and the secretarial duties were conducted by Mr. T. B. Brooks (Clarendon). Mr. H. N. Wicks delivered the opening address. Mr. C. H. Beaumont was then presented with a handsome silver-mounted mulga desk set. Mr. J. Potter, who made the presentation on behalf of the Bureau and the packing shed, stated that this would be the last Conference that Mr. Beaumont would attend in his official capacity, and referred to his untiring efforts in the interests of the fruitgrowers of the Southern district. Mr. Beaumont suitably replied. The following papers were read and discussed:—"Poultry as a payable sideline," Mr. S. Eyles (Clarendon); "Benefits of irrigation on apple trees," Mr. R. Morphett (Clarendon); "The development of a holding in the Hills District," Mr. J. C. Blakely (Scott's Bottom).

A large number of questions were answered during the Free Parliament, and the following resolutions were carried:—1. "That in view of the importance of having the correct type of oil for spraying, we ask that the specifications, namely, viscosity,

ROSEWORTHY AGRICULTURAL COLLEGE.

sulphonatable residue, volatility, oxidation, reactions, shall be given with all oils sold for use as horticultural sprays.'' 2. ''That this Conference ask the Government to take some action to reduce the price of sugar.'' 3. ''That in the opinion of this Conference the Motor Licences Act as it affects the primary producer should be amended to allow one farmer to carry another farmer's produce.'' 4. ''That all districts that are not in touch with railways should not be 'controlled' roads.'' 5. ''That the yarding fees at the Abattoirs be reduced by at least 20 per cent.'' 6. ''That this Conference ask the Government to remove the licensing of cows.'' 7. ''That the regulations relating to the branding of chilled and preserved eggs be enforced.'' 8. ''That the next Conference of Hills Branches be held at McLaren Flat.''

SOUTHERN PRODUCERS IN CONFERENCE.

Belvidere Branch held for the first time on August 18th a Southern District Conference of the Agricultural Bureau. A very representative attendance of delegates was present from the Langhorne's Creek, Belvidere, Strathalbyn, Monarto South, Murray Bridge, Jervois, Finniss, Port Elliot, Brinkley, Milang, Narrung, Hartley, Currency Creek, Rapid Bay, and Inman Valley Branches.

Messrs. A. J. Cooke, P. J. Baily (Members Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert), R. Hill, C. H. Beaumont (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary), attended on behalf of the Agricultural Bureau. Mr. H. A. Eckert presided and Mr. Cooke delivered the opening address. Secretarial duties were capably carried out by Mr. M. S. Pearce.

The following addresses and papers were read and discussed:—''The Present Position of the Primary Producer and His Prospects of the Future,'' Mr. J. M. Cheriton (Belvidere); ''Poultry on the Farm,'' Mr. J. C. Faehrmann (Hartley); ''The Dairying Industry,'' Mr. A. G. Ifould (Port Elliot); ''The Bird Pest and How it Affects Fruit Production,'' Mr. F. W. Allison (Strathalbyn).

A large number of questions was dealt with during the Free Parliament session, and Conference carried the following resolutions:—At a previous Conference a request was made for the subdivision of the Southern District for future Conferences. However, after a lengthy discussion, Conference rescinded this resolution, and decided that the next Conference be held at Goolwa, with arrangements in the hands of the Currency Creek Branch. ''That the Harbors Board be asked to place trucks on the Milang jetty to relieve users of the present haulage charges''; ''that the Harbors Board be asked to make a reduction in the wharfage charges on lakeside jetties''; ''that this Conference of Primary Producers urge that immediate inquiry be made into the cost and durability of duplicate parts of all farm machinery''; ''that the Advisory Board be asked to approach the Salesmen's Association that yard fees be abolished''; ''that a representative be elected from each Conference and appointed on the Advisory Board for the ensuing year''; ''that in view of the activities and unfair tactics of the Society for the Prevention of Cruelty to Dumb Animals, a committee be formed in each district to safeguard our interest in respect to rabbits, horses, and stock generally, and suggest that in case of action being taken in any case, evidence by two experienced farmers or teamsters be accepted in preference to inexperienced persons from the city''; ''that the producer be allowed to use washed super. bags to market barley, oats, potatoes, and onions''; ''that all members under 21 years of age be exempt from subscribing to the *Journal of Agriculture.*''

Conference concluded with an address, ''Malting Barley,'' by Mr. W. J. Spafford (Deputy Director of Agriculture).

Catering was in the hands of a local women's committee. During the afternoon the ladies were addressed by Messrs. Barlow, Anderson, and Beaumont.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on August 31st, there being present:—Messrs. H. N. Wicks (Chairman), A. J. Cooke (Vice-Chairman), A. M. Dewkins, F. Coleman, J. W. Sandford, G. Jeffery, R. H. Martin, S. Shepherd, A. L. McEwin, P. J. Baily, J. B. Murdoch, Professor A. J. Perkins (Director of Agriculture), and H. C. Pritchard (General Secretary).

School Terminal Holidays.—Following the resolution of the Upper Northern Conference, that the second terminal holidays be held concurrently with the Royal Agricultural Show, the Secretary reported that advice had been received from the Director of Education that now that the Royal Show is to be held on a fixed date each year, the school vacation for September, 1933, will commence on the second Friday in September.

RESOLUTIONS: PINNAROO LINE CONFERENCE.

Price of Super.—"That this Conference strongly protests against the high price of superphosphates." This subject will be included in the agenda for the Annual Congress.

Crop Competitions.—"That the Department be requested to supply copies of the Judge's full report of Crop Competitions to members of the Committee and Secretaries of Branches within the district." The Secretary reported that arrangements would be made this year to give effect to this resolution.

RESOLUTIONS: SOUTHERN CONFERENCE.

Yard Fees.—"That the Advisory Board be asked to approach the Salesmen's Association that yard fees be abolished." It was decided to bring the matter under the notice of the association.

S.P.C.A.—"That in view of the activities and unfair tactics of the Society for the Prevention of Cruelty to Dumb Animals, a committee be formed in each district to safeguard our interests in respect to rabbits, horses, and stock generally, and suggest that in the event of action being taken in any case, evidence by two experienced farmers or teamsters be accepted in preference to inexperienced persons from the city." This resolution will be included in the agenda of the Annual Congress.

Southern Conferences.—A resolution was passed rescinding last year's resolution that the district be divided into two districts for Conference purposes.

Yard Fees at Abattoirs.—The Hills Conference carried the following resolution:—"That the yarding fees at the Abattoirs be reduced by at least 20 per cent." It was decided to bring the resolution under the notice of the Stock Salesmen's Association.

OTHER BUSINESS.

Conferences—Holding of.—The Wilmington Branch submitted the following resolution:—"That the District Conferences of the Bureau be held in rotation instead of the present system of voting for place of next Conference." On the motion of Professor Perkins, seconded by Mr. Jeffery, it was decided that at all future Conferences *only one delegate from each Branch represented at the Conference shall vote when deciding the place of the Conference for the ensuing year.*

Life Members.—The following names were added to the roll of Life Members of the Agricultural Bureau:—Messrs. G. L. Tucker (Brentwood), F. G. Bonnin (Pinnaroo), A. Forbes (Monarto South), G. Barrett and H. G. Noske (Shoal Bay). A request from the Caliph Branch that Mr. F. J. Petch, who is not a member of the Agricultural Bureau, should be made a Life Member was not granted.

New Branches.—Approval was given for the formation of Women's Branches a[illegible] Pygery and Mangalo with the following foundation members:—*Pygery*—Mesdames J. [illegible] Heylen, R. Woodrup, J. Davill, W. H. Douglas, J. H. Foster, M. Symonds, E. N. [illegible] M. E. Heath, Misses I., A., and B. Heath, R. and D. Foster, D. Woodrup, O. I[illegible] and G. Heylen. *Mangalo*—Mesdames A. J. Turner, P. C. Cleave, F. Coles, M. Rodda, R. Crittenden, W. Munday, H. Klinberg, O. Honnemann, E. Lathlean, Misses. I. Turner, B. Cleave, and G. Lathleam.

Branch at Hope Forest.—Conditional on obtaining the sanction of the Honorable the Minister to exemption to the payment of 2s. 6d. settlers on the Hope Forest Labor Colony were granted approval for the formation of a Branch of the Agricultural Bureau; the exemption to operate for two years.

New Members.—The following names were added to the rolls of existing Branches:—Koonunga—B. A. Zwar; Marama—J. W. Corbett; Mount Pleasant—T. A. Philps; Rosedale—H. Atkins, J. Mellors; Pinnaroo Women's—Mrs. J. Rice, Mrs. J. Woods, Mrs. G. O'Loughlin; Parilla Well Women's—Miss A. Billing; MacGillivray—J. Elsegood, F. Chapman; Willowie—J. H. Johns, T. E. E. Moutford, J. F. Barrie; Strathalbyn—H. L. Formby; Younghusband—P. Dollard; Taplan—P. Burridge; Nunkeri—N. S. Gill, C. A. Smith; Mount Gambier—N. R. Aslin; Pinnaroo—C. Klein; Petina—T. L. Schultz, P. G. Roberts; Tantanoola—R. Chant; Stockport—D. Higgins; Penola—P. Riddock, P. H. G. Skeer, S. Warner, R. E. R. Lear; Mangalo—Arthur Turner, Russell Turner, H. Burton, John Burton, P. Briese, J. Evely, M. Rodda, A. Klingberg; Macclesfield—R. Scott; Penola Women's—Mrs. J. Renfrey, Mrs. E. O. Fennell; Wirrilla—C. T. R. Hall; Tantanoola Women's—Mrs. Troeth, Miss M. Pycroft, Mrs. Tooth; Warramboo Women's—Mrs. J. Crawford, Mrs. J. P. Patterson, Mrs. V. Lewis, Mrs. M. Sampson, Miss C. Sampson, Miss D. Sampson, Mrs. L. J. Simmons, Mrs. A. M. Steer, Miss A. E. Steer, Mrs. F. E. Deed; Wallala—A. Baldock; Parrakie—A. Afford; Yaninee—W. L. Wilkins; Scott's Bottom—D. Blakeley; McLaren Flat—G. Elliott, H. C. Platts, A. J. R. Powell, Chas. Air, R. Nottage; McLaren Flat Women's—Mrs. J. Smith, Mrs. B. Powell, Mrs. R. Dean; Myponga—H. White, F. Walkley, F. Waterman; Streaky Bay—S. Williams; Narridy—W. G. Johncock, J. Kingner, W. W. Hanson, G. H. Johncock, J. M. Laragy; Nelshaby Women's—Miss T. M. Franks, Miss R. Haines; Jervois—H. Bromley, A. Lockwood, E. Ely, G. G. Bryan, A. O. Forster, N. J. Hutchins, E. Joyce, G. A. Oakley, W. J. Ross, T. Ryan, T. R. Warner, E. S. Wise, E. Bartlett (sen.), E. Bartlett (jun.), T. Bartlett, B. Schultz, Clem Schultz, T. Connell, A. Pinson, W. Upton; Alawoona—Alex. Pengilly, Eric Koch; Gawler River—H. T. Fiedler, E. H. Whiteman, G. R. Hatcher, H. Giles, A. Turnbull, A. Causby, G. T. Brown; Appila-Yarrowie—E. Opperman; Goode—P. J. Rohrlach, P. A. Lange, C. H. J. Schroeder; Laura Bay—R. E. Hoffrichter, W. H. Bailley, E. J. Shearer; Butler—D. C. Stewart, H. W. Savage, Oliver Hickman; Brentwood—W. H. LePoidevin; Bundaleer Springs—T. Cleggett, L. Cleggett, F. Cleggett; Boors Plains—R. Ward, Wm. Harris, G. Harris, A. Harris, G. Smith; Elbow Hill—Rev. H. White, G. F. Wake; Beetaloo Valley—B. W. Giddings; Finniss—A. G. Roberts, M. Burzacott; Inman Valley—T. G. Hodson, J. Scott, C. Tucker; Kalangadoo Women's—Mrs. C. Bennett; Kybybolite—J. M. Wray, W. F. Staude, L. G. Harrison, P. Heffernan, A. E. Heffernan, J. Heffernan (jun.), R. Abbott, M. Williams, W. H. Michell, G. Stewart, J. B. Nolan, J. Nolan, D. Castine, W. Hahan, A. S. Shepherd; Kelly—R. G. Hall; Koppio—H. Brett, K. Low; Balaklava—C. G. Masters, R. A. Schaefer, R. J. Herriot; Kyancutta—H. Schwerdt; Greenock—A. W. Kirchner, T. Kernich (sen.), H. Werner; Laura—E. Pech, V. Pech, L. Klenig; Barmera—R. Simes, E. D. Sims, D. S. Murphy, H. Danvers, R. D. Bonnar, W. Germein, A. G. Snow, E. H. Crocker, J. Bartsch, A. J. Tonkin, F. Rawnsley, A. J. Wright, C. Winterfield, D. McRae, C. C. Chabrel, F. Andrews, H. Dunstone, A. H. Kelly, T. H. Taylor, A. C. Carbins, A. E. Cathro, V. Shepherd; Keith—B. H. Jones; Narrung—P. Hiscock, W. Hiscock, J. Hiscock, J. Hughes, G. Neale, H. Milne; Caliph—A. R. Telfer; Auburn Women's—Miss M. Darby; Clare Women's—Mrs. G. Smith, Miss N. Patullo, Miss A. Lee, Mrs. W. Miller, Mrs. W. L. Moore, Mrs. Corfield, Miss Heinrich, Mrs. G. A. Coles, Mrs. L. Dux, Mrs. A. G. Blight, Miss S. Blight, Miss L. Blight, Mrs. C. C. Gordon, Mrs. E. C. Deland; Dudley—D. I. Telfer; Bundaleer Springs—J. Cronin.

Number of new members, 210; number of present members, 7,906; number of present branches, 318.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. SANDFORD & CO., LTD., reported on September 1st, 1932:—

BUTTER.—Splendid general rains were received in most of the dairying districts throughout August, and as a result the pastures continued in good heart and supplies of cream received by the various factories throughout the State showed expansion each week. The quantity of butter manufactured therefore created fresh records, and the tonnage exported to London has kept up well. Owing to the high standard of quality of the butter submitted for export, London buyers purchased all parcels offering according to market values, so that there has been no difficulty in quitting stocks from week to week. Local trade was well maintained also, and although there were some fluctuations, these were not very great, and the market at present is steady. Choicest creamery fresh butter in bulk, 1s. 2¼d. Prints and delivery extra (these prices are subject to the stabilisation levies); well conditioned store and collectors', 8½d. to 9½d. per lb., at store door, less usual selling charges.

EGGS.—A very heavy seasonal increase in quantities of eggs was recorded during the month, but this was only to be expected, as reports from all the rural centres indicated that production would be heavy this season. Heavy quantities are now being packed for the British market, but a large proportion of the country eggs are not of a high enough standard to pass the graders for this purpose. Values eased throughout the month, and are now getting down to export parity. Ordinary country eggs, hen or duck, 6½d. per dozen; selected, tested, and infertile higher.

CHEESE.—Reports from the South-Eastern districts show that the production of cheese is keeping up well, and there seems to be little doubt but that record quantities of this commodity will be exported. The first consignments for the season reached London last week and was reported on favorably by consignees, so that there should be no difficulty in clearing the surplus throughout the season. New makes, large to loaf, 7¾d. to 8¼d.; semi-matured and matured, 10d. to 11d. per lb.

BACON.—The demand for bacon throughout the month kept up well, and fair parcels were sold interstate. Fortunately the supplies of live hogs in the Abattoirs and country markets have kept up well, so that curers are able to meet all demands for bacon out of stocks. The market has now a firmer tone. Best local sides, 8½d. to 9d.; best local factory cured middles, 9¼d. to 9¾d.; large, 8½d.; local rolls, 6½d. to 7d.; local hams (raw), 1s. to 1s. 0½d.; cooked, 1s. 2d. to 1s. 3d.; lard, prints, 6d. per lb.

ALMONDS.—There has been an exceedingly strong demand for all classes of almonds for many weeks past, and although fair supplies were offering from week to week, these were all readily cleared and buyers were unable to obtain all their requirements. Kernels also have been selling readily and stocks now held by growers are somewhat light, and prices are steady. Brandis and softshells, 9d. to 9½d.; hardshells, 5½d. to 6d.; kernels, 2s. to 2s. 0½d. per lb.

HONEY.—Stocks held by wholesalers and distributors in this State are fairly heavy, as sales have not been sufficient to clear consignments as they came along. Local demand was maintained about up to average, but interstate buyers did not operate so freely as in other years. Prime clear extracted in liquid condition, 4d. to 4½d.; second grade, 2d. to 3d. per lb.

BEESWAX.—Sold freely throughout the month. 1s. to 1s. 1d. per lb., according to quality.

LIVE POULTRY.—As usual during August the supplies of poultry from country districts are not so great as in other periods of the year, and buyers were unable to obtain all their requirements. Turkeys were offering in fairly large quantities and were moderate in prices, but well conditioned fowls and ducks firmed in values, and were in strong request throughout. Poulterers expecting a strong demand because of the Royal Show purchased more freely, and this was instrumental in hardening values. We advise consigning. Crates loaned on application. Prime roosters, 3s. 7d. to 4s. 8d.; nice conditioned cockerels, 3s. to 3s. 6d.; fair conditioned cockerels, 2s. 6d. to 2s. 11d.; chickens lower; heavy-weight hens, 3s. to 3s. 11d.; medium hens, 2s. 6d. to 2s. 11d.; light hens, 2s. to 2s. 4d.; couple of pens of weedy sorts lower; geese, 3s. 6d. to 4s. 6d.; prime young Muscovy drakes, 3s. 8d. to 4s. 10d.; Muscovy ducks, 2s. 3d. to 3s.; ordinary ducks, 1s. 9d. to 2s. 4d.; ducklings lower; turkeys, good to prime condition, 8d. to 9½d. per lb. live weight; turkeys, fair condition, 6d. to 7½d. per lb. live weight; turkeys, fattening sort lower; pigeons, 4½d. to 5d. each.

POTATOES.—5s. 6d. per cwt.

ONIONS.—New season's, 35s. per cwt.

RAINFALL TABLE

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of, and to the end of August, 1932, also the average precipitation to the end of August, and the average annual rainfall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

Rabbits and Foxes.—Mr. P. Schultz read the following paper:—"The prevalence of these pests is mostly due to neglect on the part of the landowners. In time of drought and lean years people are not aware of the fact that a few days' rabbiting would go a long way towards clearing their holdings and keep them in check. Half the battle lies with landowners to see that the netting is kept rabbit proof. The best way to get rid of rabbits is to dig out the burrows and leave them open so that the next lot cannot get established. Plenty of dogs and a gun will soon account for those remaining. Poisoning is another means of destroying, and also traps, but trapping takes a long time and one must be constantly on the job. In fumigating it is essential to see that all rabbits are chased into the burrows so that after fumigating the rabbits outside cannot dig in and allow the fumes to escape. Rabbits and their destruction involve farmers and pastoralists in heavy expense, but on the other hand thousands of men are employed killing and skinning at the present time. If skins remained at a reasonably good price all the year, rabbit trappers would soon wipe out the pest. The fox is another pest that destroys more than it is worth, but it is more easily kept under control than the rabbit. If all occupiers of land made a habit of poisoning, foxes would soon disappear. Strychnine with soda is very deadly, and the most effective bait is a young lamb. Birds of any kind or fish and mice make an excellent decoy. Poison the mouse and put it down the mouth of a mouse hole in the trail of the fox. Dogs and guns are also helpful. In poisoning foxes for their pelts, it is advisable to lay baits convenient to water so that the fox, after taking the bait, will drink, and so hasten the action of the poison. (Secretary, A. McCallum.)

June 3rd.—Present: 11 members.

Care of the Brood Mare.—Mr. A. Webber contributed the following paper:—"Most farmers work their mares up to within a week or two of foaling. There is no harm in that, providing the work is not too heavy or the hours too long. If in-foal mares are working, they should be stabled in a separate yard at night and given extra feed with a little corn. Never work a mare in foal where she has to bog through mud; this is often the cause of a mare slipping her foal. Some farmers sow a small paddock of barley for the mares, work them up to within a week of foaling, and then turn them in on the barley. This usually results in the mare gorging herself, and she becomes bloated. She may go on to time of foaling. Then there is trouble in the form of a wrong presentation of the foal, caused by the overloading of the stomach. If a little more thought was given to the mare, much trouble and a lot of mares and foals would be saved. I am not in favor of mares being moved to new quarters a day of two before foaling, especially mares carrying first foals, because the mares select their place of foaling days before the event comes off. It is as well to keep a close watch on the mares when about to foal, but if possible without being seen by the mare, especially young mares; some are very nervous and may wait for hours if they think they are watched. Very often a little help at the right moment will save a foal and possibly the mare, but unless one has had experience, do not attempt to deliver the foal by pulling too hard. If the foal is pulled back too far it may be impossible to get it forward again in the event of wanting to turn it or straighten the head or a leg. Always use disinfectant when handling the foal. If it is necessary to secure help, do so without delay as soon as there are signs of trouble. If the cleansings do not come away in 24 hours, remove them. Do not tie weights on them; this may result in some internal injury. If the foal will not suck, it is fairly safe to presume a stoppage; give a dose of oil and an injection at once. That in most cases will put things right. If one has to take the foal without assistance, disinfect the hand before inserting it into the mare. Feel the position of the foal, then proceed to straighten him and get him in position for removing. If a mare slips her foal and there are other mares in foal, keep her away from them and wash her well with strong disinfectant. Abortion is contagious.'' (Secretary, L. Mugge.)

BROWNLOW.

June 15th.—Present: 17 members and 17 visitors.

Improvement of the Farm Flock.—Mr. E. Schiller read the following paper:—''Farmers have realised that the keeping of sheep on the farm is a necessity. A small flock of sheep should be kept on the farm all the year round for the purpose of compacting the soil, keeping fallows clean, and supplying the household with mutton, and at the same time the sheep would show a handsome return for the wool. The aim should be to get the most suitable type of Merino to grow wool. What is required is a large-framed, plain-bodied sheep carrying a good fleece of medium, strong wool, density of fleece is essential. Wool that is loose and open will carry dust readily. The English bred ewe tends to lose in weight of wool after the second lambing. Avoid sheep with coarse breech wool, also with too many wrinkles over the body. A wrinkly sheep cannot stand up to hard conditions as well as the plain-bodied sheep. With lambs, however, unless they have wrinkles when they are young you cannot have a close-woolled sheep, because as the frame grows the skin is stretched, and if there are no wrinkles to supply the necessary extension the skin must become taut and the wool fibres wide apart. There are some wrinkles, however, which must be avoided even in lambs. The first is a pocket under the chin which collects and carries grass seeds, the one which runs up the side of the face below the eye, another down the side of the tail, another on the side of the flank. The art of the breeder lies largely in judicious mating, to correct faults, and to perpetuate good points. Two considerations are important in the matter of selection. Carelessly practised breeding may lead to reduced fertility and vigor. The sires and dams to be used should, if possible, be bred and reared in distinctly different environmental conditions, or, failing difference in the environment, the families from which the sires are selected should not be persisted with for too great a length of time. In choosing a sire it is always advisable to buy him as nearly as possible in his natural condition. Many young rams are so artificially forced that their development appears abnormal. Often, however, this development does not continue. Sheep should be carefully culled once a year. This is best done a few days before shearing. Examine the wool carefully—length, density, and character are the three essential points. Culling as hoggets can be done much more satisfactorily; it is a difficult job to cull ewes that are rearing lambs. Keep sheep in fair condition all the year round; if a sheep is kept in poverty it cannot grow its true type of wool and the lambs will also suffer. To make the keeping of sheep a pleasant job the owner should have good fences and build a set of yards large enough to work his flock without much manual effort. There will be little justification for erecting a wool shed on the farm. If a barn is wisely planned it can readily be fitted up for shearing. A few spare sheep hurdles should always be kept on the farm.'' In the discussion that followed Mr. A. O. Steinbomer asked when lambs should be dropped. Mr. Schiller preferred May and June. Mr. W. Roocke said plain-bodied sheep did best in drought years. Mr. H. Roocke said old ewes should be used for mating with mutton breed rams. Lambs should be tailed at two weeks of age. (Secretary, F. Roocke.)

GREENOCK (Average annual rainfall, 21.60in.).

June 27th.—Present: 39 members.

MANAGEMENT OF FARM HORSES.—Mr. Braunack read the following paper:—''The efficiency of farming to a very great extent depends on the ability of the farmer as a caretaker of his farm team, hence also the success or failure of balancing the ledger. The team should at all times be kept in such a state as to be fit for work at the shortest possible notice. It is wrong to keep horses on short rations when not working. If you give the team a spell have a recuperative tendency in view. At all times the horse should receive as much wholesome food as it can eat, but certainly no more than it desires. The manger should be cleaned up at least once a day. Ample water—three or four drinks a day—when the team is at work, is also an essential factor. The brush and comb must not be neglected for they have a wonderful result towards keeping a smooth coat, and generally upholding the health of the team. Great consideration is necessary also not to overburden horses by excessive loading. I cannot emphasise this point too strongly, for it has a very great bearing on the length of life of the farm team. Sore shoulders are in most instances due to carelessness. Collars must be kept clean from sweat and dust. It is wise to use a stiff brush on the lining now and again; this will also remove loose hair. Felt pads strapped on to the collar on both sides of a sore will permit one to work a horse without any inconvenience to it. There are numerous other cures and preventives, such as a fresh super-bag under the collar, or gall-cure, black-lead, and grease mixed into a paste. In some instances wooden collars are a great help, and above all, a good fitting collar is about the most reliable preventive of all for sore shoulders. Attention is necessary in many ways to protect the horse's condition, and a most important one is his hoof, when working on roads or rough, stony country. To neglect a tender-footed animal will reduce his condition and very much reduce the freedom of walking and thereby considerably reduce the pace of the team. The horses' teeth are neglected on most farms, but attention to these occasionally will also help towards the general welfare of the animal. The breeding of a suitable type of horse for the farm needs every consideration. This, however, seems to be generally neglected. To commence with, suitable mares are a great (perhaps the greatest) point to consider. It is folly to breed from a mare that is of little account in the team. I prefer to breed from the ablest that is procurable, for in practically all events it is found that the progeny will inherit the short-comings of its progenitor. The mare must necessarily be well proportioned and roomy, good hind-quarters, round ribs (which means round barrel), not too long in the back, good shoulders, short neck, short ears, short mouth, and eyes placed well apart in forehead, and a sound, reliable worker. The sire would be a taller horse, the same good qualities of the mare, and an active walker. Having a mare in foal, all due care must be taken when working not to overburden. Steady work right up to the time of foaling is beneficial to the mare and foal. Attention at birth is very helpful as it will prevent unnecessary labor. After foaling I prefer not to work the mare if at all possible, for this tends to check the mare's milk flow and certainly interferes with the general welfare of the foal. In this district a young horse should not be given hard work until three years of age. When purchasing, care must be taken. The horse should be firstly examined at the manger and there encouraged to eat if possible to ascertain its ability to consume food without slobbering and the condition of his teeth. It can be taken for granted that a sprightly looking animal will pass the health test, whereas, on the other hand, a sluggish animal with a drooping head may be suspected of internal disease. (Secretary, H. Wilksch.)

SADDLEWORTH (Average annual rainfall, 19.54in.).

May 20th.—Present: 15 members.

VALVE GRINDING.—Mr. R. Hannaford read the following paper:—Nearly every farmer has an internal combustion engine, either in the form of stationary engine, car, truck, or tractor. Any of these need attention at times according to the amount of work they are required to do. There are two things which have to be done more often than anything else, that is, decarbonising and valve grinding. In decarbonising, all the carbon must be scraped away with a blunt instrument from the piston tops, valve ports, cylinder heads, &c., because when the valves are ground in the engine will be open ready for decarbonising, and in grinding in the valves anyone would clean off all the carbon at the same time. There is one type of engine—that with the solid head—which requires extra dismantling for decarbonising when doing the valves. Some of the symptoms of valve trouble are loss of power, bad running, difficult starting, misfiring, back firing in the silencer. The simplest test is to pull the engine slowly over each compression by the starting handle and note what amount of compression each cylinder has. It must not be forgotten that there are other causes of bad compression, such as leaky piston, partial failure of lubrication, incorrect tappet adjustment, leaky valve plugs or head gasket. It is not a good proceeding to decarbonise an engine and leave the valves, for while the engine is dismantled the extra labor and expense in grinding in the valves is little. Most engines in use can be divided into three classes, so far as the valves are concerned:—1. The side-by-side valve engine with detachable head. 2. The overhead valve engine, also with detachable head. 3. The side-by-side valve engine with solid head to cylinders, the valves being removable through valve caps or plugs over them. *Side-valve Engine.*—To obtain access to the valves, various fittings and connections have to be dismantled in all engines. First there comes the head. The most important point with this is to slacken off the securing nuts a little at a time until they are all loose. If this is not done it is likely to lead to distortion, or even cracking of the head casting. The nuts all being off, the head should be carefully removed, taking great care not to injure the copper asbestos gasket between it and the cylinder face. The gasket should be removed from the cylinder face carefully by the aid of an old table knife, and put on one side. Care should be taken to see if the valves are numbered to their seats. In some makes of cars this is not done. It is a great work saver, so in cases where there is no number, it is a good plan to lightly mark the number on each with a centre punch, numbering from the front end of the engine. Keeping valves to their own seats saves extra work in re-grinding. Some makers use different metals or methods of construction for the exhaust valves, so that these should be kept as exhaust valves. To withdraw the valves, the valve cotter holding the spring washer on the valve stem must be withdrawn. To do this, the tension of the valve spring must be removed by further compressing it up the valve guide. To do this it is well to have the proper tool for the job. These can be bought or even made suitable for the job in hand. Extra strong springs in big heavy duty engines take some compressing, so that whatever is used it must hold securely, because if it slips or releases the fingers are likely to be injured. The spring having been compressed by raising the spring washer against it, next remove the cotter, taking care not to drop it in the valve spring chamber or it may go right through into the crankcase. While the spring is still compressed, prise up the stem of the valve with a screwdriver and withdraw the valve by hand. Now is the time to inspect the valves. Generally the exhaust valves will be found to be in the worst condition, but if one or more valves have been held up off their seats, either inlet or exhaust, burning may have taken place, and if badly burnt would render the valve or valves useless for further work, and also make it necessary to recut the seats in the cylinder casting. If any valve is badly burnt do not waste time over it, throw it out and replace with a new one. Damage to the valve seat is more serious and must be remedied, a new cylinder casting is a very costly matter. Unless the burning is very bad it is possible to re-cut the seat and use a valve of the original size, but in bad cases it is sometimes necessary to fit a new valve with a larger head. The first thing to do, once all the valves are out of the engine, is to clean them, especially the stems. Well wash with kerosene to remove all grease, then dry, clean off all hard carbon deposit both above and below the head of the valve, not forgetting the stems. Pay special attention to the valve seating, clean off all hard scaly deposit usually found in it—this will save time grinding in, also blunting the seat cutters if this has to be done. Polish the valve stems with fine emery cloth, finish the polishing, and remove any fine ridges which would favor the formation of carbon deposit. *Valve Faces.*—If the faces of the valves are in bad condition skim up the faces in a valve-truing lathe or tool. These tools can be purchased quite cheaply, so there is little excuse for not truing up the valves. *Valve Seats.*—See if the seats require any attention before grinding in the valves. If the seats are badly worn or burnt they must be cut down to obtain a new seat. Tools for this purpose can be purchased cheap, and will do the job quickly and well if used with care. In doing this part of the work great care must be taken, and as little as possible removed from the seats. It is obvious that the seat is widened by cutting down, and it is very important that the seat should be as narrow as possible, because the wider the seat the more chance of leakage and burning. Assuming that all the valve seats have been re-cut, it will be necessary, before commencing to grind in the valves, to lower the tappet screws. On some engines no tappet adjustment is provided, and after re-cutting the valve seats enough metal must be removed from the ends of the valve stems to give sufficient clearance for grinding. In some makes the push rods can be drawn out of their guides, being simply pieces of plain iron. If this can be done it is best not to reduce the height of the valve stem until they have been ground in. Clean out the valve guides with kerosene so that the valve stems drop freely through the guides. If these guides are badly worn replace them. For grinding in the valves many different preparations are sold, but all of these have some abrasive material such as emery, carborundum, &c., mixed with a lubricant such as vaseline to enable them to be handled easily. If the valves and seats have been re-cut properly there is no need to use a coarse grinding material. *Grinding In.*—Put all the valves in their own seats, commence with the end valve, lift it out and smear a small amount of grinding material in the seat, distributing it equally all around. Replace the valves, and with a screwdriver or grinding tool lean lightly on it and turn it two or three half-turns in its seat, then lift the valve by the stem and give it a slight turn, again give several half-turns, then lift as before and repeat the process several times. Withdraw the valve and with a clean rag wipe the face and the seat and carefully examine. There should be a faint grey-colored line all around the valve face and seat, and the line should be equal with and parallel with the top rim of valve. If the line is not continuous all around the valve apply more grinding material and repeat the operation of grinding. Do not over-do it, once there is a true face formed on the valve and seat any further grinding will form a ridge on the valve face. See that there is a good face line on the seat as well as the valve before being satisfied that the grinding is finished. To test this engineer's blue can be smeared over the valve face, replace the valve and revolve; this should leave the color distributed all over the seat. When all the valves have been ground in, the greatest care should be taken to remove all traces of grinding material. The valves should be washed in kerosene, the seats wiped out with a cloth soaked in kerosene, the valve guides should also be cleaned by the same means. Then lightly oil the stems and put the valves in their correct places and replace springs, spring washers, and cotters. The valve tappets must now be adjusted. It is best to follow the instructions of makers of the engine in making this adjustment, because different engines

● FULL MOON.

require different tappet clearances. It is well after a short run of the engine to check tappet clearances, because the valves tend to bed in in running after they have been ground in, thereby decreasing the tappet clearance, which may cause the valve to be held off its seat, and then loss of power will result, and probably the valve and seat damaged. Extreme clearance does not affect the power to any great extent, but makes the engine noisy, and it is to be avoided on that account. Any clearance less than .004 should be obtained in two stages. The clearance should be set to this after grinding in, and then when the engine has run for some hours at least and while it is warm, the correct clearance should be given. This work must not be done by guess, but with feeler gauges, which consist of a number of blades like those of a penknife folding into a handle each blade being of a different thickness, usually from .002 up to .019. *Engines which have no tappet adjustment.*—It sometimes happens that too much metal has been removed from the valve stem. In this case, use must be made of a cap which fits over the end of the valve stem and a supply of small steel discs which fit inside the cap. Before replacing the head of a side by side valve engine, the tappets should be set. Usually three spanners are required, two of the same size to fit the tappet screw and its lock nut, and another usually smaller to fit the flats in the tappet spindle; a feeler gauge is also required. Holding the tappet spindle, screw the tappet screw up or down as necessary, until the feeler gauge blade will just pass between the bottom of valve stem and top of screw. It is advisable to leave the spanner on the tappet spindle and move it round until it leans in one of the other tappet guides to prevent it going further. Then hold the tappet screw with one spanner, screw down the lock nut with the other spanner. Again test the clearance with feeler gauge. It will probably be found to have varied, if so, hold the tappet spindle and with a spanner try and screw the tappet screw the way required, if possible without disturbing the lock nut. For this reason the lock nut should not be done up too tight at first. *Adjustment.*—When the correct clearance is obtained screw up the lock nut tight. Do each valve in turn, and when finished give a final check over and replace valve chamber cover. The overhead valve clearance is adjusted in the same way with the exception of a few special types. Some of these have an eccentric bush supporting the rocker arm, which, when turned, increases or decreases the clearance as desired. In all cases the clearance should be tested again when the engines are warm or have done some running, especially overhead nature types.

The Chairman, Mr. L. J. Burton, who had donated £1 1s. towards the prize money, presented the prizes won in the Saddleworth Crop Competition. First, Frost Brothers, Manoora, 87.5 per cent., salad bowl; second, F. Coleman, Saddleworth, 87 per cent., silver vase; third, C. H. Behn, Riverton, 86 per cent., biscuit tray; fourth, A. J. Jones, Manoora, 84.5 per cent., jardiniere. (Secretary, F. W. Coleman.)

TRURO (Average annual rainfall, 20.02in.).

June 13th.—Present: 16 members.

DAIRYING.—In the course of an address on this subject, Mr. T. Roennfeldt, of the Greenock Branch, said:—"Butter prices were very low, but the fault was mainly on the side of the farmer, who did not give the cream sufficient attention. Although England had imported 14 million lbs. of butter from us recently, there was more second grade butter going on to the market than should be. Cows being so high priced and most of the dairy herds sold as calves previously, it was only now that herds were being built up again. Small paddocks were recommended for dairying because large paddocks were deemed too expensive. Cows did not want much exercise ,and if placed in small areas made more use of the feed. Changing the paddocks used every several days made the cows more contented. Plenty of clean drinking water was essential, especially during summer. Put down an early crop of Cape barley for greenfeed. Oats although a little better make good grazing. In top dressing grazed land superphosphate is better than sulphate of ammonia, the fodder remaining in a green stage longer with the use of superphosphate. The Jersey breed is favored over the Shorthorn because it gives richer milk although the Shorthorn produces better calves. The Jersey when acclimatised in Australia becomes hardy, although at times a reverse opinion is stated. Stable the cows at night and give a ration of 20lbs. hay chaff, 4lbs. crushed oats, 3lbs. bran, 2lbs. Meggitt's linseed meal, 1 small handful of salt, 1 handful of Cresco concentrate or 100 per cent. super. per day, if plenty of feed about, cut the ration in halves. Meggitt's is a good medicine and gives a gloss and topping to the cows, although they do not take to it at first and it can be overfed. Feed cows 2lbs. of Meggitt's per day when they are turned into the stubble. Dry bible need not be feared if Meggitt's is used. Use the skim milk for feeding pigs. The Berkshire-Tamworth cross sow put to a White boar produces a white pig required by exporters. A 1gall. cream can is recommended for use in summer for the farmer owning two cows and sent to the factory two or three times a week to overcome receiving second grade butter returns. Under-feeding cows is one of the causes of second grade tests, also feeding on Cape weed. New South Wales produces 82 per cent. of choice grade butter and SouthAustralia only 40 per cent. and 50 per cent. second grade. Three to four days should elapse before sending a newly calved cow's cream to the factory. One teaspoonful of sulphate of iron is suggested for a heifer whose milk is continually tinged with blood. (Secretary, L. S. Davis.)

GREENOCK AGRICULTURAL BUREAU.

SECOND ANNUAL REPORT.

[HAROLD E. WILKSCH, Hon. Secretary.]

[The full publication of a Branch annual report is a departure from our usual practice. The following, however, is of exceptional merit, reflecting great credit on its compiler (Mr. Harold E. Wilksch), and it is published as an illustration of a comprehensive and carefully prepared report of a year's operations of a worthy Branch of the Agricultural Bureau.—General Secretary.]

Mr. President and Gentlemen: The past year has been a very busy and successful one for the Branch, as this review of the major happenings will show. The year began with the annual meeting, held on July 6th, 1931, when the following officers were elected:—President, Mr. C. Werner; Senior Vice-President, Mr. B. Braunack; Junior Vice-President, Mr. A. Schubert; Hon. Secretary and Treasurer, Mr. H. E. Wilksch; and Assistant Hon. Secretary, Mr. M. Tregilgas. These gentlemen, with the addition of Messrs. R. Radford and W. Nenke, formed the personnel of the committee. Mr. C. Werfel was chosen as auditor. The Assistant Secretary, Mr. Tregilgas, later left the district and Mr. C. Wilksch was elected to fill the vacancy.

Twelve Branch meetings have been held, the concluding meeting being conducted on June 27th, 1932. The roll at the last annual meeting showed a membership of 48. This Branch has taken a leaf out of the books of other successful Branches, who periodically revise their rolls and if it is found that a member, for no reason other than lack of interest, has absented himself from a number of meetings, his name is struck off the roll of membership. The following of this policy has not, as might have been feared, had any injurious after effects, for although nine members were lost (this number includes resignations and departures from the district), a number of new members have been gained. During the year 11 names were added to the list of members, the membership now being 50. The average attendance at meetings, which last year stood at the fine figure of 32, has been slightly bettered, an increase of one bringing this year's average to 33. The following members have attended every meeting:—Messrs. C. Werner, W. Nenke, A. Schubert, E. Keller, H. Helbig, C. Wilksch, B. Braunack, J. B. Helbig, E. Zimmermann, and H. E. Wilksch. The last four gentlemen named have completed their second year without missing a meeting. The retiring President has given a fine lead by occupying the chair at every meeting, thus following the example of his predecessor, Mr. Radford. Members have behaved with commendable orderliness, and the business at meetings has been dispatched without hitch or hindrance —a spirit of harmony prevailing throughout. The committee has held two meetings, and on several occasions matters of main importance have been dealt with at the conclusion of ordinary Branch meetings.

The outstanding event of the year was the recently conducted Vine Pruning Competition. The fact that immediately after the last annual meeting Mr. P. Obst of this Branch won the Lower North Vine Pruning Championship Cup presented by the Royal Agricultural Society no doubt gave an impetus for conducting a competition in this district. At the competition held in Mr. C. Schultz's vineyard, Messrs. C. R. Helbig, J. B. Helbig, and A. E. Helbig, in that order, were successful in qualifying to compete in the Championship Contest, and, as the result of gaining second place for fruit tree pruning at the Light's Pass Competition, Mr. J. B. Helbig also represented the Branch in that section of the championship. Messrs. C. R. and J. B. Helbig are to be congratulated on securing second and third places in the championship for vine and fruit tree pruning respectively. As Secretary, I should like to thank members of the Pruning Competition Committee for their hearty co-operation in connection with the competition, particularly the Assistant Secretary, whose assistance in his official capacity I have very much appreciated.

An excellent and varied programme has been successfully carried out, and the interest of members has not waned. In this connection, it may be mentioned that some of the meetings have been as successful as any yet held by the Branch. We are indebted to the Chief Dairying Instructor (Mr. Barlow) for his valuable address on "Ensilage." In giving us a paper on "Poultry," Mr. A. Milway, of Light's Pass, rendered a much-appreciated service, and sheepowners have commented on the value of the address on "Sheep and Wool" delivered by Mr. W. Scott, of Truro. The District Agricultural Instructor (Mr. W. Johnston) has, in the past, gone out of his way to serve the Branch, and this year, in acceding to our request for an address on "Varieties of Cereals Suitable for Average Years" he imparted information that farmers were very anxious to obtain. Mention must also be made of the help received from Branch members. Mr. J. Clarke, in a paper on "Teeth of Horses," gave material for an instructive discussion, and the paper on "Bee Keeping" by Mr. E. Keller showed that the writer was thoroughly acquainted with all phases of the subject. Mr. Braunack's paper on "The Management of Farm Horses" was discussed with an enthusiasm that was, perhaps, unprecedented so far as meetings of this Branch are concerned, and the Secretary's address and demonstration on "Vine Pruning" was given to a large and attentive audience. It was evident that much thought had been bestowed on the seasonal reports, which the following members wrote on the respective topics:—"Livestock," Mr. B. Braunack; "Grapes," Mr. A. Schubert; "Fruit," Mr. R. Radford; and "Cereals," Mr. W. Braunack.

A number of members have represented the Branch at Conferences, and reports on the proceedings thereat have been duly given. Mr. W. Roennfeldt and the Secretary attended the Annual Congress, and at the Central District Crop Competition Conference the President and Mr. W. Roennfeldt acted as delegates. The last-named gentlemen also represented the Branch at the Conference of fruitgrowers in the non-irrigated areas, and again, in conjunction with the President, at the Conference of Lower Northern Bureau Branches. Mr. H. Helbig was our representative at the Pruning Competition Conference, and the President and Mr. E. J. Helbig acted in a similar capacity at the Haygrowers' Conference. The trip of inspection to the Roseworthy College in November of last year was an unqualified success. At the following meeting of the Branch the Secretary reported on the visit for the benefit of members who were unable to take part in the outing.

Through the agency of the District Agricultural Instructor, samples of lime were analysed some time ago and very satisfactory figures were obtained. Mr. W. Roennfeldt is conducting fertiliser tests on grape vines, pastures, and stubble ground sown to cereals. The experiments are carried out in a systematic manner and provision is made for checking the residual effects of fertilisers. This is a vital factor in determining their economic value. A number of other experiments are being conducted by different members, and the information gained therefrom will, in due course, be conveyed to the Branch.

It will be seen that a very profitable year has been spent, and we may well pride ourselves on what has been accomplished. We confidently enter our third year, knowing that we have a band of members who are one in their desire to further the interests of the Branch, for they realise that from the social side alone they are receiving their money's worth, and as a hard business investment their membership is returning dividends that the depression cannot affect. Considered from every aspect the Greenock Bureau can now be classed as a soundly constructed, welded, and tested link in the chain of Branches of the Agricultural Bureau of South Australia.

YORKE PENINSULA DISTRICT.

(TO BUTE.)

BRENTWOOD (Average annual rainfall, 15.44in.).

June 2nd.—Present: 15 members and seven visitors.

AFFORESTATION.—The following paper was contributed by Mr. E. Carmichael:—"This is a subject that, on first appearances, does not hold much interest for Yorke Peninsula farmers, as commercial forests are not likely to be a payable proposition owing to climatic conditions, and, on the other hand, there appears to be an abundance of firewood to supply the Peninsula for years in the unimproved land. Taking a far-sighted view, a vigorous policy of afforestation is necessary. Viewing the wholesale depletion in timber, and that chiefly in the most valuable native timber, during the 50 or 60 years of settlement in the district, it is evident that within the next hundred years, especially if there is a large influx of population, following the discovery of oil, firewood will become a scarce commodity. Disregarding commercial forests as unpayable, there are three features of afforestation that should appeal to the landowners of the district. They are domestic plantations, field plantations, and management of existing uncleared lands. Domestic plantations consist of trees planted around the farm buildings and the homestead, for the purpose of providing breakwinds and shelter for stock and as a very effective aid in beautifying the home surroundings. Nothing looks worse than a homestead devoid of trees; it looks bleak and uninviting. Here an immediate policy is necessary in many cases. It is a relatively simple and cheap matter to plant a few young trees—say a half-dozen a year—around the homestead. The species recommended are pines and gums. The *Pinus insignis*—while not a commercial tree in this district—makes an excellent breakwind when planted as a hedge, while other ornamental types of pines can give a picturesque touch to the homestead. However, the breakwind should not be overdone, otherwise the house and yards are likely to become a furnace in the summer. A little further afield, around the stables, etc., gumtrees are most useful; the sugar-gum does well and gives a large amount of shade, besides providing useful timber for posts and rails. In this section can also be included the planting of fruit-trees. A small garden of from 10 to 20 trees, containing a fair variety of fruits, can make a great difference to the living at very little expense. Even if the trees are not so long-lived as in gardening districts, the farmer who plants a small garden for his own use is well repaid. But such plantations will not cover the shortage that will eventually occur in regard to firewood and fencing posts. I recommend the planting of small paddocks with some native timbers. Such indigenous timbers as the sheoak, mallee, and peppermint should be planted not only to preserve our native timbers, but because of their value as fuel, and with the introduction of wood-gas tractors, that value will rise. A small area fenced off in a corner of a paddock and liberally strewn with boughs containing the seeds of these should be all the labor necessary. Given normal climatic conditions a fine clump of trees should be the result, and thus there should be an abundant supply of firewood, posts, rails, sulky shafts, etc., for the rising generation. It is surprising how the despised myall has had its potentialities overlooked. For strength and durability myall posts are supreme. Farmers in the Middle North are importing these posts for fencing purposes. An acre or two put down to these trees should obviate the necessity in this district. Even the swamp ti-tree has its uses for thatching sheds and for garden fences, and this, too, is being thinned out. Some attempts should be made to plant a few on some of our swamp areas. The planting of stands of timber seems to be useless in a district which has so many patches of scrub dotted haphazardly over the landscape, but quite a number of these are useless, for they are situated in cultivation paddocks and are so much waste ground. Such patches should be cleared right out, thus making straighter working for the team, and utilising the waste ground. Where the patches are large enough or conveniently situated, they should be fenced off and used as feed paddocks, or the smaller reserved for firewood supplies. Used for feed paddocks, they should be thinned out if too thick, all the small bushes and fallen timber removed, and the intervening spaces top-dressed. But it is evident that scrub lands used for stock agistment will in time become depleted, and so the necessity of reserving areas for the wood supply is necessary. Finally, let me say a word on behalf of the ubiquitous boxthorn. Planted as a hedge it will do away with the payment of Customs charges on fencing-wire, for a boxthorn hedge is absolutely stockproof and foolproof. In fact, the only things that can go through them are rabbits and sparrows. It is an excellent breakwind, and is a good firebreak." (Secretary, G. Tucker.)

SOUTH KILKERRAN.

Present: four members.

Mr. E. Dutschke read a short paper, "Care of the Horse".—To keep a team of 10 or 12 horses in good working condition takes a great deal of time, labor, and study. To get the best out of the horses find out in which position they work best and take good care of them. Keep the stable clean as well as the animals. Some of the most important articles are a good brush and currycomb. When the team is working, brush them down every morning, special care being taken of the shoulders. Sore shoulders are usually due to one of the following:—Collar with draft too low, collar too tight, dirty collar or dirty chin, uneven chains. See that the collar fits correctly and the bearing surface of the collar on the shoulder should always be cleaned, sweat and dirt will soon gall the shoulder. It should be possible to work from 7.30 a.m. to 5.30 p.m. with 1½ hours for dinner. Keep the team at a good even pace and they will do more work than if worked from daylight until dark. With the exception of harvest and seeding, have the team in the stable a quarter hour before sundown, so that the sweat will dry off thoroughly. A whip does not work wonders upon a horse that it is supposed to, it very often only frightens him and makes him angry, although a whip is necessary at times. Every animal must be approached and controlled in a different manner, always speak to them when moving about amongst them, be kind to them, and the animals will respond to kindness. Horses are designed to work, and daily labor for them is necessary. It is not always hard work that wears out the horse, but the rough and inhumane way they are treated. (Secretary, R. E. Hasting.)

WESTERN DISTRICT.

ELBOW HILL.

May 17th.—Present: Eight members.

Fruit Trees and Vines.—Mr. S. Hausler read the following paper:—"The collected branches of science, which horticulture and viticulture cover, are of such dimensions that it would be impossible to deal adequately with their many and varied aspects this evening. The first point to receive attention is the selection of land suitable for planting the trees or vines. Endeavor to plant the young trees in soil which is naturally fertile and well drained. Gentle slopes are suitable, as are also moisture holding alluvial soils and sandy loams. If planting on virgin soil clear thoroughly, paying particular attention to removal of roots and stumps, as these harbor insect pests. It is advisable to crop this plot the first year. Do not starve the fruit garden on poor soil merely for the sake of having it close to the house. Having selected and cleared the garden plot thoroughly as a part of the initial preparation, break the surface of soil by use of a garden plough. Where the surface has an underlying stiff subsoil it is advisable to break to a depth of at least 10in. in order to enable roots to strike out freely at a depth where severe heat and cold are not rapidly felt. The selection of suitable trees is a very important point. The most suitable varieties for this locality are the fig, almond, pear, quince, plum, mulberry, and almost all varieties of grapes. Where irrigation is possible the apricot, apple, and peach would flourish if planted in light, deep clay or sandy loams where natural or artificial drainage was satisfactory. These are the kinds which are suitable, but equally important is the particular tree selected. It is advisable to obtain trees from a reliable nursery and, if possible, to select it personally, choosing one well-worked on a suitable healthy stock, having no dead wood, a well trained, clean, straight stem which should be well rooted. Refrain from selecting large nursery trees, rather choose those of one season's growth only. The planting of the tree should be done in early winter when the soil is still warm, although the grape vine may be successfully planted in middle winter in this locality. Before planting, cut back broken roots to a healthy tissue and remove all fibrous roots which show a tendency to shrivel. All roots may be cut back to a few inches. In digging the hole in which the tree or vine is to be planted do not go beyond depth of initial cultivation, and have the bottom of hole for fruit trees sloping up towards the centre. Plant tree at original nursery depth—this is easily ascertained by an observation of the stem. Keep surface and subsoil separate and replace correctly. When planting, spread roots out evenly and have them sloping downwards with the strongest root facing the prevailing winds. Mix about 1lb. of bone dust with soil for fruit trees, one handful for grape vine cuttings, and have whole mixture loose and friable, press this down firmly around roots and put in support stake before filling the hole. The support stake is of use for determining the location of tree during tillage operations. Dig a circle a yard in radius around the tree when planted and fasten to stake with string. Do not tie string around the stem of the tree. Should the owner of the garden be desirous of cultivating his orchard by using implements, it would be advisable to plant trees or vines in squares, as this enables him to crosswork his orchard successfully. The dimensions of squares—which should be suitable—would be 20ft. for fruit trees and 10ft. to 12ft. for vines. Fence the garden in securely, even to the extent of making it vermin-proof. Particularly is this important in the early growing stages, when the tree needs every attention. In a similar manner refrain from allowing stock to play havoc with the shape of the trees and vines, even if the feed around the edges of the orchard or garden does appear to be wasted. Always take a pride in the garden; endeavor to improve its appearance and productiveness, and this feeling of pride may lead you to plant a row—or several rows—of evergreen trees along the side from which the most destructive winds blow, to serve as a break-wind. Olive trees would be suitable for this purpose as they provide excellent shelter, require little or no attention, present a pleasant appearance, and should return a small profit if marketed. The next step is to carefully tend the growing trees or vines through their infancy, because trees may easily be permanently ruined if trained in the wrong way. Bear this in mind when proceeding with the initial pruning, for it is this first pruning which counts, and it may, if carelessly performed, seriously mar the appearance and productiveness of the trees during their life. Methods of pruning vary considerably, and several correct methods may be adopted. The first pruning of trees should be done in winter while the tree is dormant. When pruning a young tree aim at a bowl shape, commencing from the main stem about a knee's height from the ground. Three buds are sufficient to leave, and these should run downward from the cut you have just made. These three buds will produce three shoots for the following year, and will set the foundation for the bowl shape, which you should be aiming at. In the pruning to follow, observe closely the following simple directions:—(1) Always cut close to a lateral or leaf bud and see that the bud which you expect to produce a shoot for the following years points in the desired direction, *i.e.*, towards the outside. (2) Remove cleanly all broken or dead wood, also cross branches. (3) Treat each cut as an injury which you are trying to heal without a trace of the original wound. When cutting away wood which is not required from the main stem, cut very close and clean, and the skin will grow over the wound. If, on the other hand, you cut carelessly, leaving a small stump, you will, besides marring the general appearance of the tree, present white ants and fungi with an excellent avenue through which to work. Observe closely these simple rules when pruning in subsequent seasons, and always prune about July, when sap is dormant. In summer pruning the only growths which should really be removed are water-shoots arising from the bottom of the tree or vine. These are easily detected and should be speedily and cleanly removed, as they do not bear fruit but extract food which should be directed to more useful channels, *i.e.*, the fruit-bearing stems. Vines may be lightly topped in early December, the effect of this process being to divert the sap to the useful wood and fruit. Topping these branches also increases the growth of second crop. Where foliage is very dense—to the extent of screening fruit—it may be advisable and necessary, in cool and wet ripening periods, to remove over-hanging leaves so that the fruit may obtain the full benefits of exposure to the sun and wind, thus hastening ripening and decreasing the danger of fruit becoming mouldy. Trees and vines should be cultivated either by hand or implement after each soaking rain. Weeds or foreign growth of any description should never be found to any great extent in a careful gardener's orchard or vineyard, for, besides stealing valuable moisture they assist in harboring insect pests and diseases which readily attack the fruit trees. To those who have seedless varieties of vines—currants and sultanas—a few words on cincturing may be helpful. This is done to check the flow, and by so doing to induce fruit to set more readily. The best time to do this is when the flowers have just blossomed, generally November to December. The method which is generally adopted is to make two very thin, clean cuts with a sharp knife around the main stem about 1/32in. apart and remove the bark in between these cuts. These cuts should not be made into the wood. If these directions are rigidly adhered to the cut will heal in a month and the temporary check of sap will result in a more satisfactory setting of fruit than would otherwise have been the case.'' (Secretary, W. Cooper.)

KYANCUTTA.

June 7th.—Present: 11 members.

The meeting took the form of a Question Box. "Foot rot and how to distinguish it." The general opinion was that foot rot was mostly confined to marshy and wet country, and there should be very little danger of it appearing in these parts. The next question was the best method to kill barley grass, and the replies given all favored ploughing it in and harrowing when convenient. The remaining question asked was: "What is the most suitable depth to fallow, and what is the most suitable implement to use. After a lengthy discussion it was the opinion of most of those present that from 2ins. to 3ins. was deep enough and that a plough was most suitable, and that every farmer should use his own discretion and use the method most suitable for his particular class of land, as the soil varied so much in this district. (Secretary, J. Dyke.)

LAURA BAY.

May 10th.—Present: 15 members and six visitors.

Bacon Curing.—The following paper was presented by Mr. H. Dixon:—"Winter is usually chosen by farmers for home-curing bacon. The weather should be studied carefully before killing—settled, cool weather being indispensable. Bleed the pig well and give the carcass a quick scald. Three parts boiling water to one of cold makes a good scald. Remove the meat from the water as soon as possible after scalding. When cleaned, hang up for at least 12 hours to cool. When cutting up, first remove the back bone and ribs, cut off the ham and trim, cut the sides in suitable pieces, and the shoulder as small as possible. For dry pickling take 1½lbs. brown sugar, 2½lbs. salt, 4ozs. saltpetre for every 60lbs. meat. Rub the mixture well into each side of the meat, put into a box or cask skin side down, and leave for 24 hours. Take out and throw away all liquid and replace the meat by putting bottom pieces at top. Repeat for a week, then turn every other day for two weeks, when the bacon should be cured. Take out and soak in clean water for eight hours, hang up to dry, rub in a little salad oil with a cloth, and hang in a cool smoke of sawdust. The sawdust must not blaze. A little saltpetre sprinkled on the sawdust gives the bacon a nice bright appearance." (Secretary, W. Edson, Ceduna.)

June 14th.—Present: 12 members and eight visitors.

Mr. F. Edson read the following paper on "Farm Management":—"The management of a farm should start from the beginning. If a man selects a new farm it would be wise to take a day or more, if required, to go over the farm and choose a suitable place to erect the house and sheds, which should be as near the centre of the block as possible. If water conservation is to be considered, it would be wise to select a place in comparatively low ground, so that all tracks leading to the homestead will constitute water runs, but at the same time the house and sheds should not be on a flat place or water will lie around the buildings. The next important step is the laying out of the paddocks, so that all the fields are handy to the homestead. If the foregoing position can be secured, there will be a good supply of water near the homestead, minimising the labor in looking after and watering of all stock, and all paddocks being handy home, the stock are always easy to procure when wanted and kept under observation if required, as well as easily accessible for working. Good fences make good stock, thus saving a lot of anxiety and work. If the fencing is for large stock, erect a fence that can be easily converted to a sheep fence, because a farmer should get a few sheep as soon as he can to cope with surplus feed and for rations. The fence for great stock should be 3ft. 9in. high, with the barb on top of the post, the next wire 14ins. lower, and the next 11½ins. under that wire, for a three-wire fence. Then to convert it to a sheep fence, two wires underneath and one between the second and third wire makes a good sheep fence of six wires; starting from the bottom, the first wire would be 7ins. from the ground, the next from that 5½, next 5½, then 6ins. and 7ins., and the barb 14ins., making a sheep fence 3ft. 9ins. high. The erection of buildings is a matter of means. If it can be managed, build stone buildings as much as possible. It is a common practice to build sheds with forks and rails, but white ants and grubs soon destroy the timber and the stock bump them loose and break them and they are constantly out of repair. The house should be on the side that the heavy winds come from, so that it will not get the dust from the sheds and stock. In the busy season all horses should be fed by 6 o'clock, and if given an hour's feed for breakfast, should be fit for work, with an hour's feed for dinner, a small feed when they knock off, then fed for the night." (Secretary, W. Edson.)

MILTALIE (Average annual rainfall, 13.59in.).

May 21st.

Mr. H. Jacobs read the following paper on "Gardening":—"Gardening, whether it be for fruit or vegetables, can be conducted successfully in this district. With a comparatively low rainfall such as we have, to plant a fruit garden we must select a site which is most sheltered from the south and easterly winds, with a soil that has a loose or sandy top, with a clay subsoil. This ground should be well-ploughed and worked down to a fine tilth one year before planting the trees. With from 15 to 20 dray loads of stable manure to the acre worked into the soil, and a good rabbit-proof fence around the orchard, the trees can be selected and planted. Obtain the trees not later than the first week in July, so that they will be in the ground and rooted before the warm weather comes, or the sap begins to rise. In planting, if the plot is not a good square shape, draw a line through the centre, measure off the number of rows it will take, and then, with a piece of light wire, of the required distance, plant the trees 24ft. apart on the square system. Cut pegs enough to peg every hole, measure off the whole plot, and peg. To plant the tree remove any damaged or broken roots, also cut back the top limbs, leaving three, if possible, branching out around the main trunk. Do not dig a deep hole; 1ft. is ample, with the soil below well loosened. Do not plant the tree deeper than it was when it came out of the nursery ground. If the soil is at all dry, give not less than a bucket of water. This having been done, with good cultivation the tree should take root and grow without any more waterings. Once the tree has rooted, the two most important jobs are pruning and cultivation. If the farmer has had no experience in pruning, get assistance from a gardener, or a very good book is available written by Mr. Quinn on that subject. Start the main arms about 18ins. from the ground. This will give room for the cultivator to get in close and keep the fruit crop low. Give the tree a cup shape, leaving plenty of space in the centre. Prune a very vigorous tree lightly and a weak tree heavily. Remove any fruit until the trees are well established. This being a dry district, spraying is not necessary as in the wetter districts, but sometimes curf leaf appears. For this disease spray with Bordeaux or Burgundy mixture when the flower buds show pink. Time and money is well spent in having a garden. One has the fruit as a reward, and a well-kept garden adds value and appearance to the farm." (Secretary, G. E. Smith.)

MOUNT HOPE.

June 21st.—Present: 10 members.

AFFORESTATION ON THE FARM.—The following paper was given by Mr. J. Vigar:—I have always been an advocate of tree planting, and have endeavoured to do a little every year. The Woods and Forest Department is the best place to procure trees, the trees from this source are certainly the lowest in price, and the Department sends out good healthy trees, equal to those which may be purchased elsewhere. For the red loam soils, with a clay subsoil, which is commonly known as heath country, the South Australian red gum stands alone; it is certainly a fairly slow grower, but it is very hardy, and is sure to come away, and do well in the first year if given equal treatment with the sugar gum, which tree I give second place. The commercial value of the red gum is unsurpassed by any other hard wood which has ever been tried in this district, and the foliage, from its early years of growth has a pretty drooping habit and always gives a beautifying effect to the landscape, and also a cool shade for stock. The red gum should never be planted too close; give it room to spread, not less than 30 feet space. The sugar gum has given satisfaction on our heath country, and is worthy of a place. The native pines also do well, and I recommend these for planting in preference to the imported types of pines, which have never done well. As an ornamental tree the almond should have more preference. It has been planted in some farms, and when given fair treatment, has proved itself suitable for the country. As an ornamental tree it is beautiful, although not attaining the large growth of the pines and gums. Its monetary returns each year should make it attractive. All other types of trees which have been tried have not given satisfaction. On the coast type of country, which has an overlying soil of light grey loam, the subsoil being chiefly white sea sand, and in some places limestone rubble, the Sheoak is worthy of note, and settlers should give more attention to its growth. If small paddocks are securely fenced, the young Sheoaks will grow from seed and do well. The dwarf gum will do equally as well as the Sheoak, it is a fast grower, and will help towards beautifying the coast lands. Both the above varieties must be protected from rabbits. I have both the red gum and the native pine growing, and although growth is somewhat slow, present prospects are that they will be large healthy trees when the Sheoak and Dwarf gum which were planted at the same time will have ceased to exist. The Tamarisk is a tree which has proved to do well on our coast lands, and if cuttings are now taken, and placed in sandy soil, they will readily take root. The Norfolk Island pine appears to do well where it has been planted. The carob is a tree I am expecting good results from; although only in its second year, it is doing well, and the sea wind has not appeared to affect it. The present seasonal rains have been good, and I hope all Bureau members will send away for their catalogues from the Woods and Forest Department, and do a little afforestation work as soon as seeding operations are completed. (Secretary R. Speed.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

COOMANDOOK (Average annual rainfall, 17.22in.).

June 30th.—Present: Seven members.

FALLOWING.—The following paper was read by Mr. W. R. Trestrail:—"Now that the farms in this district are getting into good working order, and in most cases becoming free from stumps and the biggest of the stones picked up, more attention can be paid to fallowing. The chief difficulty in laying down any one method is the number of types of soils found on the average farm in this district. Even in a 200-acre paddock several types of soil, ranging in some cases from black, sticky clay soils (when wet) to white drift sand, will be noticed. Strictly speaking, each class of soil needs a different working to ensure best results, but this cannot be done when the soils are so patchy, and all that can be done is to work on a general scale. The problem of stony soils in this district always presents a big difficulty, because the more they are worked the more work they make by bringing more stone to the surface. However, taken as a general average, the soils of the district can be classed as sandy loam, with occasional sand rises that require careful treatment with regard to fallowing so that they do not drift. The correct method of handling sandy soils is becoming a question of the utmost importance in South Australia, because in all of the comparatively low rainfall country a fairly large proportion of the soils is of a sandy nature. These soils are, generally speaking, easy to clear and to work. Also in their virgin state they were offered on very reasonable terms by the Government and men with limited capital and stout hearts and arms were afforded an opportunity of taking up the vocation of farming. To derive the best yields from the land it is necessary to fallow. Not half the wheat grown locally is produced on fallow, hence the small returns of recent years. Fallowing is not a new method of farm practice. It has been in use for hundreds of years. The

Roman farmers used fallow to increase their wheat yields. The pioneers of farming in all countries of comparatively small and uncertain rainfall soon discovered that continual cropping was unprofitable owing to the depression of the yield. The benefits of bare fallow were soon discovered, and this system gained a firm footing. Under Australian conditions it is definitely stated that to obtain wheat crops where the annual rainfall is below 20in., bare fallow is necessary. The outstanding advantages of bare fallow for grain growing are as follows:—(1) It conserves soil moisture; (2) it increases the available plant food in the soil; (3) it ensures a clean, firm seed bed; (4) it distributes farm work more evenly throughout the year; (5) it controls weeds; (6) it leads to increased wheat yield, especially if there be a dry spring. (1) The sun is ever drawing moisture from the soil, and the wind also dries out moisture. The fallowed land acts as a shade in keeping the sun's penetrating rays from searching from the deeper soil the stored moisture. This may be termed a mulch of fine soil that is the result of the land being stirred up, pulverised, and partly set. The water that passes through this top layer of fallowed soil is very much slower in evaporation. Slight stirring of the soil after every rain is so important to conserve moisture (2) This follows on the first point. The soil is full of bacteria. The conserved moisture creates favorable conditions for the growth of bacteria, which require a favorable temperature, sufficient supplies of soil moisture, sufficiency of air in the soil, and the presence of a base (lime or gypsum) to combine with a nitric acid formed. All these conditions are found in well worked fallow. This is one of the most important factors in the production of the bigger yields of wheat. This point is often overlooked, moisture and air producing a nitrogen or plant food for the coming crop. In Victoria tests have been made and the amount of nitrate nitrogen formed in fallowed and non-fallowed soil to a depth of 5ft. in typical Wimmera soil is as follows:—Fallowed land, 91.9lbs. nitrate nitrogen per acre; non-fallowed land, 21lbs. nitrate nitrogen per acre. Locally it is not possible to store that quantity of plant nitrogen, because the soils have not that depth of earth, but unquestionably the land derives much benefit in making available more plant food for the plant. A 15bush. crop of wheat requires 21lbs. of nitrogen per acre. (3) The District Agricultural Instructor (Mr. R. L. Griffiths) never tires of making this point plain to mallee farmers. It is one of the problems in sandy soils to form a firm seed bed. To attain this is not the matter of a week or two or one or two workings. Judicious cultivation, rain, and sheep are necessary. No mallee farmer can possibly afford to be without sheep; they assist very materially in a consolidated seed bed. That is why the sowing of oats is often recommended on drifty soils at time of fallowing, so the sheep will pack the soil, while the oat plant will also bind the land. Soil likely to drift cannot be worked or made smooth, because it will probably cause trouble if high winds are experienced. To obtain a clean seed bed, weed seeds must be allowed to germinate and be killed, and this takes some time. (4) Bare fallow distributes the work of the farm more evenly throughout the year. Successful farming entails a close application to detail. Preparation of the seed bed and the sowing at the right period of the year are very important. Bare fallow enables the farmer to spread his work more evenly throughout the year. Rush periods and long hours with a tendency to slum work are abolished. Hasty ploughing, followed by the seed drill or combine, means a poorly consolidated seed bed, dirty crops, and poor yields. Summer fallowing should commence after harvest should a good rain fall, and winter fallow as soon as seeding is finished. In this district it is not wise to work the fallow too much before harvest, but if summer rains fall use every favorable opportunity to work the land, kill weeds, and consolidate the seed bed. (5) Fallowing helps considerably to control weeds. Each time the soil is worked the weed seeds are brought nearer the surface where they germinate. Most weeds require air as well as moisture to cause growth. This is what is done each time the land is harrowed or cultivated. Never work deeply with the cultivator or all the work is undone. Fresh weed seeds are liberated and the seed bed destroyed. After every rain in summer and autumn, get busy and kill weeds. Sheep, as previously mentioned, are a very valuable asset in keeping fallows under control from weeds. Lastly the aim of fallowing is that of increased yields. One cannot do better than quote figures from the Government Statist that have been recently published, showing the superiority of crops grown on fallow. In a very good season the difference in yields per acre is much less than in less favored seasons, as will be seen by the following tabulation. These figures represent total South Australian yields:—

	Yield per Acre.		
	1930-31.	1929-30.	1928-29.
Grown on—	Bush.	Bush.	Bush.
Fallow	14.31	9.07	10.74
Non-fallowed	7.57	2.84	3.65
Total	11.81	6.40	7.79
Rain, April-November	13.71in.	9.57in.	9.39in.

Of last season's wheat crop 2,385,441 acres sown on fallow yielded 35,325,997bush., averaging 14.31 bush. an acre, and 1,685,929 acres sown on unfallowed land yielded 12,767,105bush., averaging only 5.75bush. an acre, thus making the State average 11.81bush. an acre. Conclusions: From practical experience and facts and figures fallow pays. Fallow early. Use where possible the share plough. Keep weeds down with sheep and with subsequent working, especially if summer rains fall. Be careful not to go too deeply to disturb the seed bed. It pays well to fallow new land, especially if any porcupine was growing in the land previously to the burn. No crop can be successfully grown in this soil until the sourness and the roots of the plant have been ploughed out. Each farmer must choose his own method of working according to the type of soil on his farm. Experiment, and be careful to note and tabulate the results, and this will be a valuable guide in the coming years. (Secretary, W. Trestrail.)

MOORLANDS (Average annual rainfall, 14.76in.).

June 15th.—Present: nine members.

Co-operation.—The following paper was contributed by Mr. R. Nicholls:—"One of the most familiar expressions in the English language is 'Mind your own business,' and no doubt there are many occasions when the remark is justified, either as a rebuke or advice, but if everyone were to concentrate exclusively on minding his or her own business the world would be a very poor place in which to live. The higher and more intelligent animals do not mind their own business, in that sense at all events: they co-operate. Wolves hunt in packs for increased hunting strength, and deer form herds for mutual safety, whilst everyone knows the wonderful co-operative work of ants and bees. Man, the highest animal of all, has attained the state which we call civilisation only by joining with his fellows, and the greatest nations have been those whose people worked together. Co-operative societies have sprung up all over the world, and much has been said and written about the undoubted advantages of co-operative marketing. Co-operation, like charity, begins at home and there are many opportunities for practical co-operation in this and every district in Australia. It would be hard to find a body of men more willing to help one another in time of trouble than farmers, and, when directly approached, they are always ready to explain their methods of production. But there is room for more co-operation in little things, and little things always count. Take, for example, the rabbit pest. It is notorious that a man

Metter's Master "Nuoil" Windmills

Most Reliable, Efficient, and Durable.

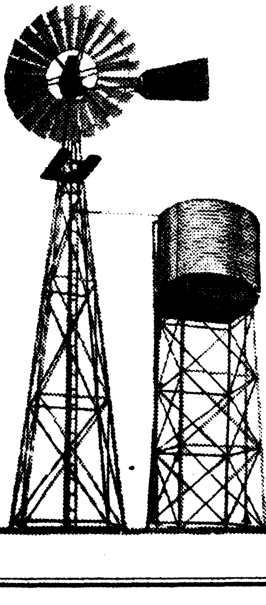
"No fear of a Drought With a Metters about."



may constantly reduce the number of rabbits on his property and still suffer damage to his crops because his neighbor is not co-operating with him by also setting traps or cleaning out stone heaps. In a recently settled area like this the control of rapidly spreading weeds is almost an impossibility, but where conditions allow, it should be regarded as a public duty to exterminate them. Then there is the very important matter of the boundary fence. No one but a decided optimist would expect a man to carry co-operation to the length of allowing his neighbor's sheep to get fat on his growing wheat. These are only a few of the ways in which local co-operation can be carried out, but the exercise of a little consideration and occasionally putting yourself in the other fellow's place, will discover many more. Practice co-operation on your farm. Co-operate with those about you, treat the team as partners not four-legged machines, and just as you expect the horses to co-operate with each other, co-operate with them by attending to their needs and ailments at the proper time. It is also possible to co-operate with yourself by bringing the best that is in you to bear on your work. Accept the co-operation of others who are waiting and willing to co-operate with you in the Government experimental and instructional departments. These departments are in existence—not for the purpose of finding someone a soft job—but to help you to co-operate with nature and thus get the best out of your land. Last, but by no means least, is that very practical co-operative association, the Agricultural Bureau, which, if properly used, should be as valuable as Roseworthy College. Experience—the hardest but perhaps the most successful of teachers—may show you a better way of doing a thing, and, unless you consider it such a brilliant discovery that you intend taking out patent rights for it, it is up to you to bring it to the notice of your fellow-members—possibly it will save someone pounds. Bring your troubles along as well, providing they are not financial or domestic, because healthy discussion will frequently produce a way of overcoming them. Mind your own business by all means, so far as minding it means attending to it, but remember that co-operation is only an every-day application of the golden rule: 'Do as you would be done by.' " (Secretary, R. Wilmshurst.)

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

June 18th.—Present: 27 members.

Poultry.—Mr. A. Frahn read the following paper:—"Poultry is a very important sideline on the farm because grain put aside for poultry will be profitable throughout the whole year, and contribute considerably towards housekeeping expenses. A good laying strain should be kept. A house built with galvanized iron, bolted on to iron instead of wood, is advised, so that if troubled with lice or tick a fire can be lighted in the house and the vermin destroyed without any harm being done. There should also be a breeding pen or two in every poultry yard, big enough for about 10 hens and one rooster. The fowls can then be penned to get eggs for setting. Drinking water should be changed regularly; if neglected, it is likely to cause disease amongst the birds. Poultry should be fed on pollard occasionally. When feeding with wheat, throw the grain where the fowls have to work and scratch for their food. Green feed, such as cabbage and lettuce leaves or a patch of lucerne will be found very useful. Hens should be penned about June, so that they will be laying for August setting. If penning White Leghorns, Black Orpinton hens will mother the chicks better than the White Leghorns. Poultry should have a good, roomy house, with suitable roosts made with wood. Iron roosts are too cold in winter. Another important point is to see that the birds always roost in the house, not on top of the farm implements and along the back of the horses' mangers. "Clucky" hens, if not wanted for setting purposes, should be taken off the nest and penned until they go off the brood. Eggs should be picked up regularly; it is the stale egg that helps to keep the market for country eggs so low. Poultry houses need special attention and must be cleaned out regularly. When deciding to get rid of surplus or unprofitable stock, pen and fatten them; good conditioned birds always bring the best prices. Turkeys hatched about June will be ready for sale when there is a good demand, but they are more difficult to rear than those hatched in September or October, because then the weather is much warmer." (Secretary, C. F. Altmann.)

PARILLA (Average annual rainfall, 13.91in.).

June 20th.—Present: Eight members.

Fat Lambs.—Mr. J. Wallis read the following paper:—"As a mother for fat lambs the Crossbred ewe may present many advantages over the Merino, but at the present they are not available in any great number, whereas the Merino can generally be secured in an even line and in almost any number. As a mother for fat lambs I suggest a large-framed, long-woolled Merino ewe, the Leicester cross is a good type offering a higher lambing percentage, better shaped, and early maturing progeny, and able to stand wet and cold conditions better than pure Merino. A ewe for this purpose should not be too old, a six-tooth to full mouth being a good age. As soon as the ewe shows signs of teeth failing she should be cast out. Young ewes often prove poor mothers, and if mated to British bred rams lambing losses are much heavier. *Mating*: The selection of a good ram is a very important factor in breeding fat lambs. The Suffolk or Dorset Horn are good sires for early maturing lambs. When mating ewes the number of rams should not be limited, and if possible more than one should be turned in with the ewes as they then work better than if alone. Not more than 50 ewes should be mated to one ram. The ram should be strong and healthy; if either too fat or too low in condition the result may not be very satisfactory. A ram generally becomes slower as he gets older, and should not be relied on after 'full mouth.' In warm weather or when the rams are carrying heavy fleeces, it is sometimes difficult to get the rams to remain with the flock, in such cases it is a good plan to yard the sheep overnight. The ram should remain with the flock from six to eight weeks, and if possible a fresh ram should be added during the last week or two to catch up ewes which may have missed. The ewes should be in good store condition, but not fat, when mating. The ewes should be crutched a month before lambing is likely to commence. As the lamb is a source of revenue close attention should be given to the flock as soon as lambing commences, and assistance given when necessary. Tailing should be done when the lambs are about two weeks old, they then recover more quickly from shock than if older. It also prevents coarseness and staggyness of the wether lamb. It is not a good plan to wait until all the ewes have finished lambing before tailing because some would be much too old. In order to prevent tetanus, tailing should be done in a well grassed enclosure rather than a dirty yard. *Marketing*: Lambs should not be weaned before disposal, but sent straight off their mother. It is essential they carry 'bloom,' and therefore should be grazed on the best of pasture. Hand feeding can never replace grass so far as lambs are concerned. When a lamb is from 14 to 16 weeks old—if given plenty of good feed—it should be fit for market and weigh from 70lbs. to 75lbs. live weight. It is a mistake to keep them until they become too heavy, they often lose their 'bloom' and realise a lower price. *Trucking*: Every care should be taken when trucking. Lambs are very easily damaged, and the use of sticks or lifting by the wool should be avoided as much as possible.'' (Secretary, C. Foale.)

RAMCO.

April 26th.—Present: Six members.

The Hon. Secretary read extracts from a Bulletin, ''Preservation of Posts.''

A further meeting was held on May 16th, when the discussion on the above subject was continued.

PRUNING.—Mr. E. Leishman (District Horticultural Instructor) delivered an address at a meeting held on June 13th. In the course of his remarks, Mr. Leishman said trees were pruned with the object of producing fruit, not wood. Cutting should not be too hard or too much wood growth would develop. It should be the aim to get the tree between strong and weak; weakness went to fruit, strength to wood. Each tree should be treated individually. Pruning of the vine depended on the strength of growth. If growing strongly, the vine should be given plenty to do. He considered competitions along the river had improved pruning. The aim was to establish a standard of pruning on a commercial basis. *Analysing of Orchards by Simple Tree Records.*—The factors in orchard practice that had received the most attention in the last decade were cultivation, pruning, manuring, pest control, &c. The inherent qualities of the trees had received considerable attention during recent years, with the result that more care was given to the selection of stocks and bud wood than was formerly. Beyond the general questions of soil and climatic limitations, however, comparatively little attention had been given to the important matter of orchard environment, and especially in relation to cultural practices. Unquestionably much, if not most, of the wide variations of yields of trees was due to differences in environmental conditions as related to cultural practices and may be overcome partially through an appreciation of this fact by the grower. To determine the relative efficiency of the orchard, a method of analysis was suggested over a period of four years. He believed that its use would do much in indicating the nature of the cause of failure and increasing the production of the average orchard. Most growers thought of their orchards in acres or blocks, but should consider the individual tree was the ultimate unit, a fact not sufficiently appreciated by the average grower. The progressive dairymen would not question the value of herd testing, and the keeping of production records to the fruitgrower was of just as much importance. A simple method must be adopted; elaborate means could not be undertaken without a fair amount of expense. The fact of keeping data of actual tree records had been the principal point in deterring growers from undertaking orchard analysis. By long practice a grower became an expert in estimating the yield of trees in cases. A system which could be adopted was as follows, taking into consideration a normal full crop for the year and divide in the following classes:—(1) Very poor; (2) poor; (3) medium; (4) good; (5) very good. *Estimating on the Basis of the Size of the Tree.*—For all practical purposes three groups were necessary, viz.:—:—(1) Trees failing to make a return equal to the amount expended on their care could be referred to as "boarders" bringing on classes very poor and poor; (2) trees producing sufficient fruit to approximately meet productive costs and not showing a profit could be called "self-supporters" under the class medium yields; (3) those making a return in amount larger than their share of production costs were "profit bearers," class good and very good. In segregating the orchard into those three groups the practical consideration was to determine the causes of consistent variation. Possibly in the majority of cases, low production was the product of environmental factors which might be wholly or partially remedied. In taking those tree records over a four-year period, one would probably find the three classes arranged themselves in groups instead of being scattered here and there. If that was the case it was obvious that one or more general factors were affecting the trees and pointed to environment. Those causes might be possible to correct by means of changes of orchard management, such as draining, cultivation, irrigation, manuring, &c. The information gained by simple orchard analysis would be extremely helpful, and possibly remedy the causes so as to improve the orchard production. Mr. Leishman then answered many questions. He favored multiple furrows in watering orange trees, being better than few furrows for long period, allowing water to sink where not needed. The Washington Navel orange was a bushy tree of pendulous habit, much of the shape of a globe with a thin skin. Off-type was more upright in growth, the fruit having a gross skin and often corrugations at the stem. Thompson's Improved was only improved in the skin, which was thin, and ripened early. It had not the juice nor flavor of Washington Navel, and did not produce many dry oranges. Replying to a query as to manure for vines, he favored super and sulphate of ammonia (3 to 1), and it was preferable to apply half before the first irrigation and the remainder before the end of November. For a single manure sulphate of ammonia gave best results. (Hon. Secretary, J. J. Odgers.)

AILMENTS OF STOCK.

Address by Mr. F J. J. Petch to Alawoona Branch of the Agricultural Bureau.

Sand.

From a good deal of experience and examination I have come to the conclusion that when horses are carrying an unknown quantity of sand, it is better to try and get them accustomed to stable feed and to settle down without having recourse to medicines credited with the ability to shift sand. More sand is moved by extraneous causes than by medicine. Between harvest and seeding is the worst time for horses collecting sand, especially if the crop has any burnt off patches in it. The obvious course is to take horses up before they have become loaded with sand. We cannot, however, always do this for many reasons, so must take the chance. After taking the horses up and beginning to work, it will be found that odd ones will go off their feed, whilst not actually bad. Leave them out of work, and it will be found they will settle down, but may have a slight attack later on. Once the team gets over that stage it will be found that they may go through a whole seeding without sickness, and when turned out on good feed or crop later will get rid of the sand by Nature's process. Carefully note the team and its work, and if any sickness from this cause occurs, it will generally be found that there is a cause for it. Either the team has been hurried the previous day or over-pulled or something unusual has happened. Therefore avoid anything out of the ordinary. It is quite possible to run horses in a stubble paddock and get them loaded with sand, but if left there until green feed comes along there will be probably no deaths. Take them out and shift them smartly for a few miles, and the chances are that the aged horses in the mob will die. What happens is that the unusual has brought about an upheaval in the stomach which has lifted the sand collected there and forced it along the bowels. The small bowels having a greater "capillary attraction" than the large bowels, pass this sand along whilst causing the animal to have violent colic attacks. When this sand reaches the big gut along the bottom of the belly, it collects and the capillary attraction being less, the horse is unable to pass this sand before inflammation sets up and kills him. More sand is moved by other causes than medicinal, and the best way to move sand is by getting the animals out on to good green feed, when the succulent juices will do more than medicines for this ailment. The construction of the horse's stomach is such that it lends itself to the collection of sand and similar matter, whilst cows, sheep, &c., are not so affected. It must be remembered that should horses get so bad that action is necessary, it is worth while to give purgatives—warm water injection, &c., in the hope that the quantity of sand to be moved is less than was thought

WHEAT.

Horses from time to time get access to wheat and gorge until they become ill. If the animals have been discovered before the effect of wheat gorging is noticeable, push them along for a mile or two at a good pace after giving them all the water they will drink. This helps the bowels to pass along the wheat. Look out for symptoms of colic in the early stages and give physic in the shape of 1pt. linseed oil, followed by 4 drams of aloes in a ball. Usually it will be found that those horses which show signs of colic very early after getting the wheat will be those that have got the least quantity and will quickly recover. Look out for the horse that is likely to die unless treated quickly. This horse should be bled from the jugular vein about half-way between the collar and jaw, and about 1gall., or in some cases a little more, taken. For the novice it may be well to say that to bleed a horse is quite simple, and is done in the following manner:—Pass a cord around the neck and tie it fairly tight; clip hair away from the place selected to bleed. The vein will become enlarged when the cord is tied and easily seen. Mark the place right over the vein with indelible pencil and then cut through the outer skin. When the skin goes back, the cut should be right over the vein. Cover a sharp knife with the finger and thumb and pierce the vein in a longitudinal manner. Catch the blood in some article of a certain size as a guide to the quantity. When finished, release the cord, pass a pin through both edges of cut and wind cotton around each end. Next day pull out the pin. Disinfect before and after. Carbonate of soda is used extensively for this complaint, and being of an alkali nature, should counteract the acid gas generated by the wheat. Some farmers think that because the seat of the trouble is the feet and legs, blood should be drawn from the leg. This is not so. The idea is to reduce inflammation and blood pressure as quickly as possible, and this can best be done by drawing off from the jugular. Another advantage is that in the neck the animal is less likely to contract tetanus than the leg. There are two peculiarities of the horse. One is the predisposition to turn cartilages into bone on the slightest provocation and the other is for any general derangement of the system to bring about laminitis or inflammation of the feet. Mares after heavy foaling and horses after extraordinary exertion are subject to founder, and the same treatment of bleeding as for wheat is recommended.

STRANGLES.

This is a disease that must run its course, and is better left to Nature than interference by man. Good food, attention, and good nursing are all that is required, and all that can be given by the ordinary man. Steam the nostrils in bad cases and allow

Nature to burst the abscess when ready. Premature interference only brings about a sort of bastard abscess which may disappear and form again internally and cause death. Tracheotomy is performed in only very few cases.

MILK FEVER.

This occurs in cows in a fat condition after (generally) the second calf. Conditions predisposing to it are, in addition to fat condition, heavy milkers and easy birth. The trouble usually occurs about 24 hours after calving, but can be much later. The cow staggers and finally goes down and gradually becomes unconscious. No medicine is required. Milk fever outfits are obtainable for about 12s. 6d., but usually are in a perished condition when wanted. A quill from a turkey's feather put in a bike pump is quite satisfactory for inflating the udder. Tie with ½in. tape and take off tapes after cow has got up. On all occasions use plenty of disinfectant both for hands and instruments. This complaint is easily recognisable, easily cured, and can be treated by any man or woman of average intelligence.

PINK EYE IN SHEEP.

This is known fairly generally by the above name, but is contagious ophthalmia. Pink eye is a virulent form of influenza in the horse; sheep become blind and wander off on their own, often in circles, and get away from the mob and become exhausted. The eye is covered with a white or pinkish film. Place all sheep so affected in a small yard and feed with long hay. They will feel this with their feet and will eat more readily than from a trough, which they might fall over several times before finding out that it contains food. Use boracic powder or eye lotion for the eyes and the disease will run its course generally in 10 days to a fortnight.

Mr. Petch then dealt with parturition at some length, and quoted many of his own experiences, and endeavored to show members how easily they could help themselves and neighbors by giving a little wise and careful assistance at this time. Although for cases of malpresentation there were various instruments obtainable for the assistance of the operator, they should never be used except in the hands of very experienced and careful men. Most cases could be successfully dealt with by commonsense and careful manipulation of the human hand and arm, which, after all, for this purpose is one of the finest instruments ever made. Great care and cleanliness should be observed at all times, and all inside work done quickly, but not hurriedly. After malpresentation or a heavy birth it should be remembered that several things could happen. The back bowel may be inverted, the womb inverted, mare may get inflammation of feet, &c. For the other two conditions the animal should be stood with her head downhill, and after carefully washing in warm milk or mild disinfectant and removing all dirt, the rectum or womb should be gently returned. Give a dose of laudanum, and if necessary securely fasten on a "gate" or wire up lips to prevent recurrence. Mr. J. Pengilly asked if there was any preventive for milk fever and would fasting help. No known preventive but fasting for a time, say a few weeks on half rations, before calving, would help considerably. A cow might have it one year and miss the next. Mr. P. Paull had a cow with tongue protruding from mouth, being stiff like a piece of wood. The complaint was known as wooden tongue, caused by a rag-fungus, and the mouth and other parts of the body became hard and ulcerated. A veterinary surgeon should be called in, as this disease was communicable to man, and care should be exercised when dressing. In cattle the treatment was to give ½oz. doses of potassium iodide daily; scrape away the affected parts, and swab with idoine solution (1 in 20).

PARILLA WELL.

Formed on March 13th, 1912, the Parilla Well Branch of the Agricultural Bureau celebrated 20 years' of active work by a social evening in the local hall on Tuesday, August 16th. There was a very large attendance of members and visitors, the chair being occupied by Mr. J. Ferguson, jun. An excellent report, covering the work of the past year, was presented by the energetic and capable Secretary of the Branch (Mr. E. C. Slater), and the Branch owes much of its continued success to the enthusiastic efforts of this officer. Opportunity was taken of the occasion to present Messrs. J. E. and J. W. Johnston, J. G. and G. B. Pahl, A. M. Nordhaussen, and J. S. Ferguson certificates conferring on the recipients the honor of life membership of the Agricultural Bureau, the certificates being handed over by Mr. F. C. Richards (Assistant Secretary of the Agricultural Bureau). These gentlemen are six of the foundation members of the Branch, and on receiving the certificates, each spoke of the value of the Bureau to the man on the land. It is interesting to report that Mr. J. E. Johnston, who was the first Chairman of the Branch, has again consented to occupy the chair for the ensuing year. Messrs. A. Bone, H. G. Fewings, and A. Young, of the Pinnaroo Branch, congratulated the members who had received their life membership certificates, and a strong plea was made for the young men of the district to "stick to the Bureau" and take a live interest in its work. A novel feature of the evening was the excellent variety of costumes worn by the dancers, and prizes were awarded for the best sustained character and best "old time" dress, the judging being done by Mesdames Young, Hawthorne, and Mr. Richards. Supper was provided by the ladies, and a most enjoyable evening concluded with dancing interspersed with vocal and musical items.

TAPLAN AGRICULTURAL BUREAU.

FIELD DAY.

Attended by a gathering of 30 members and visitors, and boys from the senior classes of the local school, the Field Day held at Mr. D. R. Hampel's farm on Tuesday, August 23rd, was agreed by all present to be the most successful fixture held under the auspices of the Taplan Branch of the Agricultural Bureau. During the afternoon Mr. P. H. Suter (Senior Dairy Instructor) gave an interesting demonstration on the points to look for when selecting a good dairy cow. The visitors were then entertained at afternoon tea by Mrs. Hampel, after which, in company with Mr. R. L. Griffiths (District Agricultural Instructor) and Mr. F. C. Richards (Assistant Secretary), they inspected some of the crops on Mr. Hampel's farm, which consists of 1,045 acres, all of which are cleared. Mr. Hampel has been on his holding for six years, and has 600 acres under wheat this year; 200 acres being on fallow. Wheats sown include Nabawa, Waratah, Early and Late Gluyas, Gallipoli, and Sultan, the last mentioned being a particularly fine crop, and prospects point to the best harvest since Mr. Hampel has been in the district. His farm average last year was 13bush. to the acre.

Field Day, Taplan Agricultural Bureau, August 23rd, 1932.

Mr. W. J. Hammond (Chairman of the Taplan Branch, and one of the oldest residents of Taplan) has been in the district for 21 years, and is a keen supporter of the Agricultural Bureau and the Department of Agricultue. He believes that whilst the present situation calls for very careful expenditure of public moneys, the Department of Agriculture should be the last of the Government Departments to be unduly hindered in the excellent work which it is doing for the man on the land.

Like many another Branch of the Agricultural Bureau, the Taplan Branch has had its ''ups and downs,'' and much of the credit for holding the Branch together during the drought years, when interest was inclined to lag, is due to the enthusiasm of the Secretary, Mr. P. R. Hodge, of Nangari. He came to the district in 1912, and for two years worked a farm on shares with Professor Angus, a late Director of Agriculture. Mr. Hodge sold his plant and livestock in 1916 to enlist, only to be turned down as unfit for active service abroad, and then continued share farming until 1920. In 1921 he was allotted a scrub block of 1,200 acres, of which 850 acres have now been cleared; 500 acres are under crop this year, the principal wheats sown being 300 acres of Nabawa and Ranee. Present indications are that the season will be one of the best since he has been farming in the district, and with a rain to finish off the crops early in September, and a reasonable price for wheat, farmers will be well on the road to recovery.

Another of the original settlers of the district is Mr. E. H. Schultz, of Nangari, who, with Mr. W. J. Hammond, are the only remaining foundation members of the Taplan Branch. He took up his block of 1,320 acres of scrub land in 1914. At this time the district was not connected with the Loxton water supply, and water had to be carted from Paringa at a cost of 9s. per 1,000galls. This year he has sown 500 acres of wheat, 125 acres of which are on fallow. His favored varieties are Nabawa, Ford, and Gluyas. So bad have rabbits been this year that Mr. Schultz was forced to stop fallowing to deal with this pest, and in the course of eight weeks' trapping 2,000 rabbits were taken off the property and sent to the freezers at Renmark at prices ranging from 2d. to 5d. a pair, and Mr. Schultz said, ''there was good money in them at that.'' In 1929 Mr. Schultz ''banked'' his all on the turn of the season, and had under crop 1,900 acres, but this disastrous undertaking resulted in a return of 32 bags of wheat. He considers the prospects for the season to be excellent, and on present indications expects his farm to average a yield of eight to 10 bags to the acre.

The evening meeting was one of the largest the Branch has ever held, there being quite 150 persons present. Short addresses were delivered by Messrs. Griffiths, Suter, and Richards, and the evening concluded with a supper and dance.

So successful has this form of meeting proved with all Bureaux, that it is suggested that those Branches who have not included a Field Day on the programme of meetings for the year should, with the co-operation of the Officers of the Department of Agriculture, endeavor to do so.

SOUTH AND HILLS DISTRICT

MILANG (Average annual rainfall, 14.96in.).
July 16th.—Present: 13 members.

FARM POULTRY.—Mr. W. Yelland read the following paper:—The average farmer of this State does not look after his poultry to the best advantage. The writer recommended them to join an association to help market the eggs, which should be of 1⅞ozs. to 2ozs. for export. The collecting of eggs should not be neglected, and at all times should be packed and graded carefully. Feed first-class food, give clean water each day, and do not force a pullet to lay until five to six months old. The writer recommended White Leghorns for a first-class, all-round bird. He then dealt with the export trade, saying that there were over 68,000 cases of eggs and pulp shipped from South Australia last year, the shipping period being about five months of the year. South Africa was our biggest competitor, as they were three weeks nearer the London market than Australia. The discussion was very spirited. (Secretary, L. Yelland.)

MYPONGA (Average annual rainfall, 28.94in.).
June 16th.—Present: 16 members and 12 visitors.

FARM BUILDINGS.—Mr. R. C. West read the following paper:—"In the construction of farm buildings the main object is to have good solid posts which will stand in the ground as long as possible from rot and white ants, and for this purpose the sand gum is the best procurable in this district. To save trouble it is advisable to straighten the outside edges of the posts with an adze before erecting. Rails let or housed into the post makes the best and strongest job. When putting in the posts the chief point is to have the building set out square; a simple method is to remember the figures 3, 4, and 5. If one measures 3ft. along one side and 4ft. along the other side, it must be 5ft. across the angle for the building to be square. The next item is the rafters and pitch of the roof. All rafters should be strong enough or strutted to stop sagging. On an ordinary lean-to roof the most common mistake is the pitch; too often the mistake is made of not giving the roof sufficient fall. Plenty of fall not only keeps the shed cooler, but it also tends to keep it more watertight by allowing the water to get away quickly. A fall equal to 2ft. 6in. in 10ft. is little enough; in a gable roof a 3ft. pitch in a 12ft. span is small enough. With the roof purlins a mistake often noticed is that the timber is placed flat instead of on edge. This weakens the roof, because timber, say 3in. x 2in. on edge

C. F. ANDERSON, Poultry Expert.

will hold twice as much weight as 3in. x 2in. flat. Gable roof purlins are often put on the flat to cut down the sizes of the ridge and the fascia boards, but this saving is not very much, unless the roof is a very big one. In putting on the iron always give at least a lap and a half joint at the edges, with one over and one under sheet, and it should be nailed every other flute. A shed put up properly will last for years without any repairing. The interior of a cowshed is an important part of the farm buildings, and should be so arranged that everything is as convenient as possible. Provide a passageway at the back of the bails for feeding purposes. In a cowshed where there is a double row of bails, have all the heads facing towards the centre, instead of towards the sides. If this is done it is a simple matter to have a small truck loaded with fodder, and go along to every bail and feed up. It is a good plan to have a wide passageway, so that at one end room will be available for bins to store bran, chaff, &c. A cowshed built on these lines will save a lot of work and running around. Each bail should be at least 5ft. wide to give ample room for getting in and out. The height should be at least 7ft. The mangers should be made of iron; these are easier to keep clean, and a tin drum cut in halves lengthways makes a good manger. The floor should be well drained and formed with a hard waterproof material such as asphalt, hard stone, brick, or concrete, and all joints and cracks filled with impervious material, so that no liquid can soak into them. The floor to each bail should have about a 2in. fall to allow for good drainage. In mixing concrete with ordinary river gravel, 6 or 7 to 1 is recommended. The dairy is the next most important building. Erect one with cavity walls either of brick or iron or some other material. The cavity causes a draught and keeps the building cool, while a roof with a good pitch is essential. A good cool roof for a dairy is one thatched, with iron over the top. The dairy should be as far as possible—though not to be inconvenient—from the cowsheds or yards, fowlhouses, and pigsties. A dairy should be at least 10ft. x 10ft. x 8ft. All openings should be covered with fly wire. Adequate ventilation is essential. A good pigsty has as much influence on the rearing of good pigs as the feeding. A pigsty should be at least 10ft. x 8ft., with a lean-to roof at least 5ft. high at the lowest point. A mistake often made with pigsties is to have the roof so low that one cannot get into them to clean them out properly. Further, such a roof makes the sty very hot in summer. The sty should be free from drafts. Ordinary wooden slabs make a good warm floor in a sty. In the farrowing pen a rail should be placed 6in. to 8in. from the floor to prevent the sow from injuring any of her young before they find their legs properly and are able to get out of her way. The floors should be at least 9in. above ground level. The stable should be fitted up in a manner similar to the cowshed, with a passageway behind the manger for feeding purposes. A stall for one horse should be at least 6ft. wide and 16ft. deep. A deep stable is most convenient because it provides room to hang the harness at the back of the horse. The floors should be similar to that of a cowshed and well drained. Attached to the stable should be the chaffhouse. One building lacking in this district on a number of farms is an implement shed. Most implements are left in the open, but an implement shed is as much to the profit of a farm as any other part of the equipment. To have success with poultry, good,

Mount Compass Field Day, September 1st, 1932.

warm sleeping houses are necessary. The fowlhouse should be at least 5ft. high at the lowest point for a lean-to roof, 6ft. high at the front and no deeper than about 8ft. If the house is too deep the sun only gets to the inside at the back for a very little while in the early morning. Where fowls are kept in captivity the ground space should be at least 4 square ft. per bird. The fowlhouse should face north-east in order to get the maximum of sunshine. Along the front of the house enclose at least 2ft. from the ground with iron to guard against draughts. The perches should not be any higher than a foot from the ground, especially for heavy strains of fowls. (Secretary, C. Martin.)

TEARING THEM OUT

is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed. It develops the power of 260 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

CROWN LANDS.

LANDS OPEN TO APPLICATION.

Applications will be received until 3 p.m. on Tuesday, October 18th, 1932, for lands in the Hundreds of BARNA, BLACKER, BOOTHBY, BROOKER, BUCKLEBOO, BURGOYNE, CAMPOONA, CARALUE, CARAWA, CARINA, COLTON, COOTRA, CUNGENA, FINLAYSON, GOODE, HAGUE, HASLAM, KIANA, KOONGAWA, LAKE WANGARY, MAMBLIN, MANGALO, McLACHLAN, MILTALIE, MINBRIE, MINNIPA, MITCHELL, MOODY, MOORKITABIE, MORTLOCK, MOSELEY, PYGERY, ROUNSEVELL, SHANNON, SMEATON, SOLOMON, STURDEE, ULYERRA, VERRAN, WANNAMANA, WRENFORDSLEY, YADNARIE, and in the Counties DUFFERIN, KINTORE, and ROBINSON.

Full particulars are published in the *Government Gazette* of September 8th, 1932, and plans and detail may be obtained on application to the Director of Lands, Box 293A, G.P.O., Adelaide.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

R. S. RICHARDS, Commissioner of Crown Lands.

S. R. WHITFORD.
Minister of Agriculture

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, &c.

Non-Irrigated Fruit Districts, at Tanunda—Lone Pine Branch, November 1st. (Secretary, Mr. T. Fromm, Tanunda.)

The opening session will take place at 10.30 a.m. Papers, questions, &c., should be forwarded to the General Secretary, Agricultural Bureau, about a fortnight before the date mentioned above.

Ensilage and Grass Hay Competition.

The South Australian Advisory Dairy Board, in conjunction with the Department of Agriculture, is again promoting competitions for grass hay and ensilage amongst the dairyfarmers in this State.

Entries will be invited from dairymen in two (2) districts, viz., the Hills and South-Eastern districts, and will be restricted to those who are milking not less than seven cows.

Trophies and certificates will be awarded in each of the four competitions, and successful competitors will receive prizes as under:—

First	£3 3s. and certificate.
Second	£2 2s. " "
Third	£1 1s. " "

Entries will close on January 4th, 1933. Full details and entry forms can be obtained from the secretary, L. S. Smith, c/o Office of Minister of Agriculture, Education Building, Flinders Street, Adelaide.

Lower North Pruning Competitions.

The Secretary of the Lower North Pruning Competitions (Mr. J. S. Hammat) has pointed out that the name of Mr. J. B. Helbig was omitted from the list of competitors in the Langdon Parsons Cup as reported in the September issue. Mr. Helbig has scored a total of 1,089½ points, made up as follows:—Year 1931—trees 364, vines 183 (547); year 1932—trees 360, vines 182½ (542½). In the grand total for the two years his position is therefore eighth on the list.

Codlin Moth Control.

Any departure from old established ideas in the control of codlin moth is generally received with suspicion. Mr. C. H. Beaumont (District Horticultual Instructor) states that bandages are recommended as an aid to the usual spray programme for the control of codlin moth. The bandages are treated chemically so that there is no necessity for examination during the season. The larvae which shelter under them are killed by the solution used in the preparation of the bandages. Corrugated bands properly prepared are now available, and a 2in. band seems just as efficient as a wider one. It is said that 1,000 grubs may be killed by one band. The United States Bureau of Entomology have had the matter in hand, and the system is also being tried in Victoria.

VETERINARY INQUIRIES.

[*Replies supplied by Veterinary Officers, Stock and Brands Department.*]

Secretary, Agricultural Bureau, Arthurton, reports mare stiff in legs. Reply—If the stiffness occurred after foaling it may be a form of laminitis. Give a drench of raw linseed oil 1½ pints, turpentine 2 tablespoonsful, and that she be turned out into a good grazing paddock. No green crop or grain should be allowed.

the one oil that always
stands up

Greenock reports a Jersey heifer which had a swollen udder before and after calving, and is now desirous of drying her off prior to calving next October. Reply—Give the heifer 1 dessertspoonful of alum in 1 pint of cold water twice a day for three days, and gradually dry off by milking away a smaller quantity of milk at each milking. If possible, it is preferable to have her dry at least a month before her next calf. Cut down her green feed and grain. The condition is not serious providing there is no change in the character of the milk, such as presence of clots, stringiness, accompanied by heat and pain of the udder, which latter condition would indicate true inflammation of udder due to germs.

Secretary, Narridy Agricultural Bureau, asks treatment for itch on legs of horses. Reply—The application of the following preparation is recommended:—Lysol 1 tablespoonful, sulphur 2 tablespoonsful, raw linseed oil 1 pint.

Murraytown reports horses lame, but show no signs of bruises or swelling. Inquirer also asks treatment for blood worms. Reply—From the information supplied it is difficult to determine the seat of lameness. In the event of your still failing to locate the cause, turn horses out for six weeks, but before doing so examine carefully the hoof of each lame foot to see if any injury (puncture or bruise) is present. Treatment for blood worms is as follows:—(1) Starve horse for 18 hours. (2) At the end of that time give following drench for draught horse:—Raw linseed oil 1½ pints, oil of turpentine 4 tablespoons. Shake thoroughly and drench carefully. (3) Subsequently give 1 tablespoon of Fowler's solution of arsenic in a small damped feed night and morning for 14 days. (Buy a 1lb. bottle). (4) Feed on good quality chaff, bran, and crushed oats.

Secretary, Kangarilla Agricultural Bureau, reports cow with blocked teat. Reply—It appears that there is a constriction of the lower end of the teat canal. The only satisfactory way of overcoming this trouble is to have the teat operated on by a qualified veterinary surgeon. The repeated use of a teat dilator would perhaps help to overcome the trouble to some extent, but such relief would more than likely be only temporary, and unless very great care were taken with using the teat dilator, an attack of mammitis might result. The surgical operation suggested is a relatively simple one and will give permanent relief without risk if properly performed.

Taplan asks treatment for a dog with stomach worms. Reply—For three days feed the dog on bread and milk, or porridge and milk, and a little lean meat. Procure from a chemist half a dozen "Nema" capsules size 187 for adult dogs. A dog weighing 8-10lbs. give one capsule, a dog weighing 10-20lbs. give two capsules, a dog weighing 20-30lbs. give three capsules. For 12 hours before administering the capsules do not give any food, and after administering give no food for two hours. A small dose of Epsom salts (1 teaspoonful dissolved in water) two hours after capsules have been given will assist. To administer the capsules—open the dog's mouth by squeezing the cheeks and drop them in according to the number required, and follow with a little water to make the animal swallow. If the dog does not swallow straight away, do not hold the jaws together, but allow the animal to drop the capsule and try again.

Secretary, Bunora Agricultural Bureau, reports—(1) *Aged mare who periodically gets very lame.* (2) *Is it advisable for a stallion to serve mares every 10 days until they go "off season"?* Replies—(1) Blister the swelling with a biniodide of mercury (1 in 8) blister, which you will have to obtain from the nearest chemist. To do this, clip the area, wash thoroughly, an ddry. Then rub in blister for 10-15 minutes. After application tie mare up short, so that she cannot get nose down to part. Wash swelling next day. Turn out for four to six weeks. (2) The mare's period of oestrum is a week, and there is a three-weekly interval between each heat. It is advised—more especially for uncertain breeders which nevertheless come regularly on heat—that service be given more than once during one heat, and service during later part of heat is more likely to be successful than if performed at its commencement. It is not advisable that mares which have worked hard all day should be taken in the evening two to three miles to stallions, and again, mares should not be served before going to work. They should be rested both before and after service.

ANNUAL REPORT ON PASTURE IMPROVEMENT, KYBYBOLITE EXPERIMENTAL FARM, 1931-32.

[By L. J. Cook, R.D.A., Manager.]

A very fair pasture season was experienced during the year 1931-32. Of 657 acres of fields and plots that have been used solely for pasture production during recent seasons, 367 acres (56 per cent.) of them recorded increased carrying capacity over the previous season 1930-31, so that the number of livestock carried on the farm has not been much affected. Throughout the agricultural year—April 1st, 1931, to March 31st, 1932—an average of 1,464 sheep and 122 cattle have been kept on the farm, as against 1,322 sheep and 122 cattle during the previous 12 months, showing an increase of 142 sheep. However, 35 more acres of temporary pasture were available this season, the area cultivated for crops being 114 acres, and 138 acres left for temporary pasture, as compared with 149 and 103 acres respectively during 1930-31. Hence, 795 acres of fields of pasture, with the stubble feed of 114 acres, have carried 1,464 sheep and approximately 70 head growing cattle wholly throughout the season, as well as provide full pasturage for 40 milking cows during the pasture growing period, and portion of their feed during the balance of the season. Also 24 horses have had part-time grazing; 200 acres of the general pasture fields were not top-dressed this season, a saving of 10 tons superphosphate being made. These fields, however, had received good applications in the past, and the feed was not greatly affected this season through not being top-dressed.

THE SEASON.

The season commenced well; good germinating rains were received during March, and these were followed by a splendid fall of 1½ins. in mid-April, thus ensuring good early feed. April recorded approximately 2ins. of rain, 70 points above the average, which was most valuable to pastures. May produced just the average for that month, and being very well distributed, combined with mild temperatures, pastures developed really well. A heavier recording than usual was received during June, but again the distribution was good, and little or no check was made in growth until late in the month. July falls were a little less than usual, and pastures generally survived the cold months well, and the usual check in growth at this time of the year was not severe. August rains were sufficient, although below the average, whilst September started well, but a dry period commenced in mid-September, which persisted until February of this year. This period of 140 days is one of the longest without a useful rain on our records, and for the time of the year such a period has never been experienced since weather records have been taken here. Less than 1in. of rain was recorded for the four months, October to February. Good falls, registering nearly 2ins., occurred during the first half of February, and these were followed by useful rains in March. For the full 12 months 19½ins. were registered—more than 2ins. less than the average for the past 26 seasons.

The season promised well for clover growths; Subterranean and the naturalised clovers germinated well, and maintained good growth throughout winter and early spring, but abnormal spring conditions spoilt their finish, and although there was sufficient summer feed, the clovers did not mature well. Only a little meadow hay was obtainable, and there was a considerable shortage of clover seed for stock to use as autumn feed. The early autumn rains, however, retrieved the position, and prevented what might have been a serious shortage of paddock feed during March, April, and May of this year, and enabled the carrying capacity of fields to be maintained. The native-rooted grasses, *Danthonia* species, had another good season, and benefited greatly by the early autumn falls. The naturalised annual grasses, such as barley, silver, and Brome, were prominent during the season, especially during winter. Their seeds during early summer were troublesome to stock, but not to such an extent as usual.

Of the sown grasses, *Phalaris tuberosa* gave the most feed, especially during winter. Wimmera Rye gave good returns, and Perennial Rye very fair results. Both the latter suffered more during the cold months than others, but Perennial Rye benefited greatly by early autumn rains, responding as well as the native Wallaby grass.

Once again phosphate-dressed pastures showed to good advantage over non-fertilised lands.

The following table shows the monthly rainfall of recent years, compared with the average for the past 26 seasons:—

	1926. In.	1927. In.	1928. In.	1929. In.	1930. In.	1931. In.	1906-31. In.

IMPROVEMENT OF NATURAL PASTURES WITHOUT CULTIVATION.

The work of top-dressing natural pastures with phosphatic fertilisers and lime was commenced in 1919, additional plots have been added from time to time, and at present there are 17 plots being used for this work, 13 of which are 3½ acres in area and four are 5 acres each. Since 1921 careful records of the grazing secured from the plots have been kept. For the past three seasons the plots have been continuously grazed in rotation by five flocks constituted according to the estimated carrying capacity, and a separate flock has been used for each type of fertilised pasture. That is, A and AA flocks, 20 sheep, have been used on unmanured land, 24 acres; B flock of 35 sheep has been used on 14 acres of land improved with superphosphate; C flock of 48 sheep has been used on 17 acres of land improved with lime and superphosphate; while D flock of 20 sheep has been used on 10½ acres of land improved with rock phosphates. Another small spare flock has been used on all fertilised plots, as required to utilise excess feed. Similar type and aged sheep have been used in each flock, constituted of 25 per cent. Waite Institute Merino wethers, and 75 per cent. Kybybolite Comeback ewes. Through the assistance of the Waite Research Institute we have been able to weigh these sheep monthly, and so keep a definite record of their development on this type of pasture.

The pastures have consisted principally of Wallaby Grass, Barley and Silver grasses, annual naturalised clovers, and of recent years one of the *Erodiums* has appeared on them in fair quantity.

The following table shows the fertiliser applied, with date, and rate of applications; whilst Table 3 shows the grazing results secured:—

TABLE 2.—*Fertilising of Natural Grazing Test, Kybybolite*, 1919-32.

Plot.	Total Fertiliser per Acre.	Date and Rate of Application.
1	1 ton Aluminium Phosphate Rock (412lbs. phosphoric acid)	1919, one application
2	11cwts. Aluminium Phosphate (227lbs. Phos. Acid)	1919, one application
	6cwts. Aluminium Phosphate (124lbs. Phos. Acid)	1920-25, 1cwt. per annum
	306lbs. 45% Superphosphate (63lbs. Phos. Acid)	1926-31, 51lbs. per annum
3	1 ton Lime (Calcium Carbonate)	1919, one application
	1 ton Lime (Calcium Carbonate)	1929, one application
	13cwts. 36% Superphosphate (240lbs. Phos. Acid)	1919-31, 1cwt. per annum
4	11cwts. Calcium Phosphate Rock (232lbs. Phos. Acid)	1919, one application
	6cwts. Calcium Phosphate Rock (127lbs. Phos. Acid)	1920-25, 1cwt. per annum
	3cwts. 82% Calcium Phosphate Rock (126lbs. Phos. Acid)	1926-31, ½cwt. per annum
5	1 ton Calcium Phosphate Rock (422lbs. Phos. Acid)	1919, one application
	10cwts. Calcium Phosphate Rock (420lbs. Phos. Acid)	1929, one application

6-year period			0·94	—	—	—	—	—	—	0·23	-	—	0·11	—	—

In commenting on the above results, it is to be noted that the plots easily carried the flocks assigned to them in good store condition. There was a good carry over of feed from the previous March, and the flocks had good grazing through the autumn, winter, and spring months. The quick response of native grass to this year's February rain greatly assisted the pastures of these fields to complete the season satisfactorily. The Comeback ewes dropped lambs in August, and carried them on the plots until weaned in January. Five or six plots showed an appreciable increase on the previous year, eight plots carried approximately the same grazing, whilst only two showed much reduction. Plot 1, which has not been top-dressed since 1919, showed a depreciation of ¼ sheep per acre, and Plot 10 also had a leaner season. Plot No. 8, which has now received 180lbs. 45 per cent. superphosphate for six years in succession, produced the most feed, and carried approximately four sheep per acre. Plot No. 7, dressed with 90lbs. 45 per cent. superphosphate, was second with 3¾ sheep per acre, and showed the greatest improvement (¾ sheep) for the season. Plots Nos. 3 and 9, dressed with lime and superphosphate, and gypsum and superphosphate respectively, also carried over 3½ sheep per acre.

In comparing the six plots that have now provided results for 11 consecutive seasons, the four dressed with phosphatic fertiliser only have increased the carrying capacity approximately 1.06 sheep per acre, or 126 per cent. above that of the check plot; whilst the lime and phosphate-dressed plot has increased 2.27 sheep per acre, or 270 per cent. above the No Manure plot, and 1.21 sheep per acre, or 64 per cent., above the phosphate-only dressed plots. On Plot No. 1, which has not been dressed since 1919, the growths are thinning, moss is appearing rather plentifully, clovers are disappearing, and the land is reverting back to the unmanured type.

The addition of a small quantity of water soluble phosphate to Plot No. 2 is continuing to give an increased carrying capacity—and although of recent years this plot has only received half the quantity of phosphatic acid that has been given to Plot No. 4, its growth of pasture has been better. Since the change in application, Plot 2 has averaged 2.46 sheep per acre, as against 1.82 by Plot 4—over ½ sheep per acre better.

Plot No. 5 carried very good grass, and is continuing to show an advantage in applying large quantities of acid soluble phosphate at comparatively long intervals, in preference to applying this form of fertiliser in small quantities annually, as is done in the case of Plot No. 4. This year it yielded 0.67 sheep per acre better than Plot No. 4. For the whole 11 years it has been 9 per cent. better, and for the past six years it has been 15 per cent. superior to No. 4.

In the following table the averages of all plots for the past six seasons have been grouped together according to the various forms of fertiliser, and shows an interesting comparison of returns and value.

TABLE 4.—*Comparative Summary of Six Years Grazing on Top-dressed Natural Pasture.*

Fertilisers Applied.	Area.	Sheep per Acre.	Increase Over No Manure.	Increase Over Superphosphate.	Increase Over Rock Phosphate.	Annual Cost of Fertiliser per Acre.	Annual Cost of Fertiliser per Sheep.	Profit per Acre per Annum. Sheep at 10s
	Acres.		%	%	%	s. d.	s. d.	s. d.
Lime and Superphosphate (W.S. Phos.)	8½	3·01	234	21	63	11 0	5 3	10 1
Crushed Limestone and Superphosphate (W.S.P.)	5	2·60	189	5	41	8 3	4 10	8 9
Superphosphate (W.S.P.) .	10½	2·48	176		34	5 8	3 7	10 2
Gypsum and Superphosphate (W.S.P.)	3½	2·24	149		21	10 9	8 0	2 8
Ephos Phosphate (Cit. and Acid Sol. Phos.)	5	2·04	127		10	6 0	5 3	5 5
Crushed Rock Phosphate (Acid Sol. Phos.)	10½	1·85	106		—	4 2	4 5	5 4
No Manure (Check Plots)	8½	0·90	—		—	—	—	—

These results show that the greatest return of feed has been secured from the use of lime and superphosphate, lime applied at the rate of 1 ton per acre every 10 years, and superphosphate applied at the rate of 1cwt. annually. This fertilising costs approximately 11s. per acre per annum. Valuing sheep at 10s. each, this fertilising shows an annual profit of 10s. 1d. per acre.

The crushed limestone dust and superphosphate application is second in quantity of production, and this fertilisation has been at similar rates, namely, 1 ton per acre of limestone every 10 years and 1cwt. superphosphate annually. The dust costs approximately 22s. 6d. per ton on the land; that is 2s. 3d. per year, plus 6s. for superphosphate, 8s. 3d. for an extra return of 17s., or 8s. 9d. profit. The applications given to the three plots dressed with superphosphate only have averaged at rate of 105lbs. per acre per annum, and have returned a yield of 2.48 sheep per acre—third position on the table. The cost of this fertilising is 5s. 8d. per acre, and the extra return gained of 1.58 sheep means a cost of 3s. 7d. per sheep, and a gain of 10s. 2d. per acre profit when sheep are valued at 10s. each per annum. This shows superphosphate to be the cheapest fertiliser per sheep, and to be equal with lime and superphosphate in profitableness.

Rock phosphate with an average annual application cost of 4s. 2d. is the cheapest per acre, but is a little dearer per sheep, and the profit only shows at 5s. 4d. per acre per annum.

In further comparing these fertilisers the following Graph No. 1 shows the yearly carrying capacity secured from the use of Lime and Super No. 3, Super. only Plot No. 7, Calcium Rock Phosphate Plots Nos. 4 and 5, compared with check plot of No Manure Plot No. 6. It is to be noted that the super. plot was only commenced in 1924, and the increase in production has been marked during the last two seasons, this year exceeding the production of lime and super. for the first time.

1930-31
1931-32

With reference to the type and variety of plants growing on this series of plots, again we were unable to make any true botanical analyses of the growths of the various fertilisations, but from general observations, the only plant to make noticeable increase in quantity is a species of *Erodium*, which has become more in evidence on the limed plots. Wallaby Grass and annual grasses remain more or less constant, and except on the more recent reclaimed plots, the naturalised clovers are remaining at about 30 per cent. of the herbage. Rooted Cat's Ear did not make its usual heavy summer growth. Thistles that had infested the lime plots of recent years were not so plentiful on these this season, but increased on other plots, that have been carrying a lot of stock.

In considering the behavior of sheep flocks used for grazing these natural pasture plots, the following table and graphs are of interest in showing the results gained from the Comeback ewes in the flocks.

TABLE 5.—*Weights of Sheep and Wool, Natural Pasture Plots*, 1930-32.

Flock.	No. of Ewes.	Kind of Fertiliser on Plots Grazed.	Average Weight of Ewes.			Average Weight of Wool per Sheep.			
			8/4/30.	31/3/31.	30/3/32.	17/10/30.		21/10/31.

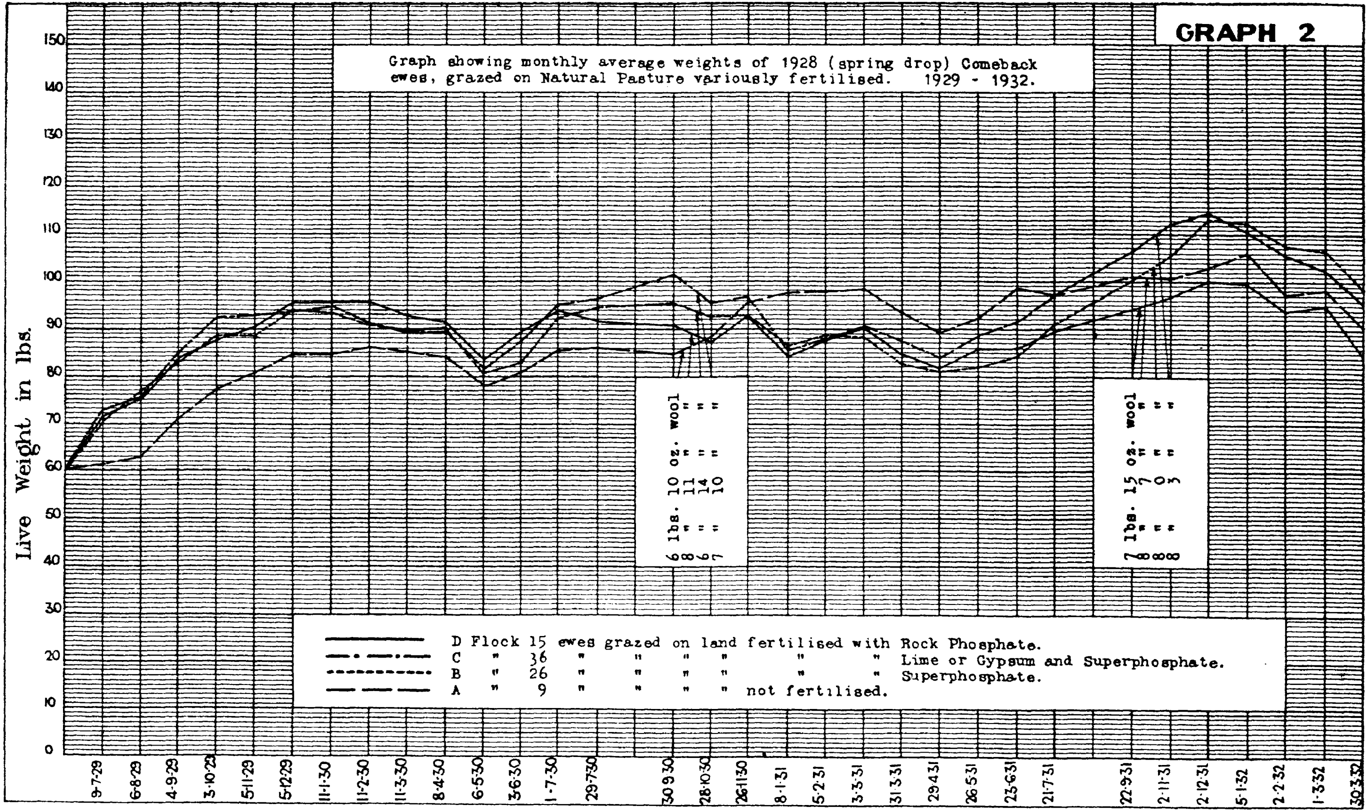
B	26	Superphosphate	81	50	44·5	57·3	3·07
C	36	Lime, Gypsum, and Super.	89	66	39·2	52·6	3·39
D	15	Rock Phosphate	80	73	44·2	48·5	2·04

All of the ewes in the above flocks are of similar age and breeding (1928 spring drop), and were selected as even in type and development in May, 1929. Since then they have been kept wholly on the one class of pasture. Except from March 25th, 1930, until May 5th, 1930, and from March 19th, 1931, until April 29th, 1931, when the 86 ewes were mated together as one flock with Merino rams, they have been pastured on the respective plots shown in above table. The table shows the average weight of ewes in each flock taken at the beginning and end of each grazing year, the average weight of wool shorn in October, 1930 and 1931, and constitutes 12 months' growth in each case (ewes were blade-shorn each season). Results of lambing are shown as percentages of lambs marked, and the average weight of lambs taken at weaning. Also the actual grazing results taken from the various groups of plots is shown in the final column.

Graph 2 shows clearly how the weight and development of ewes vary throughout the season; each year there has been a steady and regular increase during the pasture-growing periods May to December, and a loss of weight during autumn, when the feed was mostly dry.

It is noticeable that during the first season, as hoggets, the ewes developed comparatively well and evenly; the second season, 1930-31, their first breeding year, the flocks generally did not develop so well, and three flocks, B, C, and D, suffered rather badly in the autumn of 1931. However, this last season, 1931-32, with the exception of Flock D, much improved average weights have been recorded, Flocks B and C reaching 113 and 114lbs. in December, and falling only to 98 and 95lbs. this autumn.



GRAPH 2

Graph showing monthly average weights of 1928 (spring drop) Comeback ewes, grazed on Natural Pasture variously fertilised. 1929 - 1932.

In considering individual flocks, A Flock, that has been developed on unmanured pasture, showed a much slower development than the others on fertilised land. The first season they did not reach nearly the weights of the others, although they gained and lost weight at similar times. During the second season they were also well behind until late in the season. As maiden ewes that year they produced very few lambs—only 22 per cent.—which accounted for the fact that in average weight they were superior to other flocks during autumn and winter months of 1931. They yielded 66 per cent. lambs this season, and since then their weights have receded, and Flocks B and C have improved beyond them. A glance at Graph 3 shows that the ewes in this flock that reared lambs this season have felt the effects greatly, and their weights are some of the poorest in the flocks, whereas the dry ewes in this flock have continued to maintain good weights, and at present are the heaviest of the flocks. Considering that the flock has only averaged 44 per cent. lambs for the two breeding seasons, it could have been expected that a greater yield of wool would have been produced. Instead, although the flock in the two seasons has produced 3ozs. per head more wool than Flock B, it has yielded 12ozs. and 25ozs. less per head than Flocks C and D respectively, and these latter have also produced 75 per cent. more lambs.

It must be noted that to supplement the amount of unfertilised feed, Plot No. 9 in unmanured clover land series has necessarily had to be used at times by this flock, which accounts for the carrying capacity of plots grazed showing at 1.08 sheep per annum, which is higher than unfertilised virgin land, and should, if anything, give the flock an advantage.

Of the three flocks grazing on fertilised plots, Flock C on lime and supered land, so far, has proved to be the most productive, combined with good health. Flock D has produced most wool, and practically equal in lambing percentage to C flock. The condition of the ewes, however, in D Flock, especially those that have reared lambs this last season, is poor, and as bad as those in A Flock. It appears to show that the strain of two comparatively good lambings has been severe on these. C Flock has produced equal proportion of lambs, and the ewes have stood the strain better, and are now in much better order for the next breeding season. Ewes in Flock B suffered heavily after the first lambing, and a lot were in comparatively low condition for the second mating. However, the flock had a light lambing, and the ewes have improved this last summer, and the flock is now in equal condition with C Flock for next season's breeding.

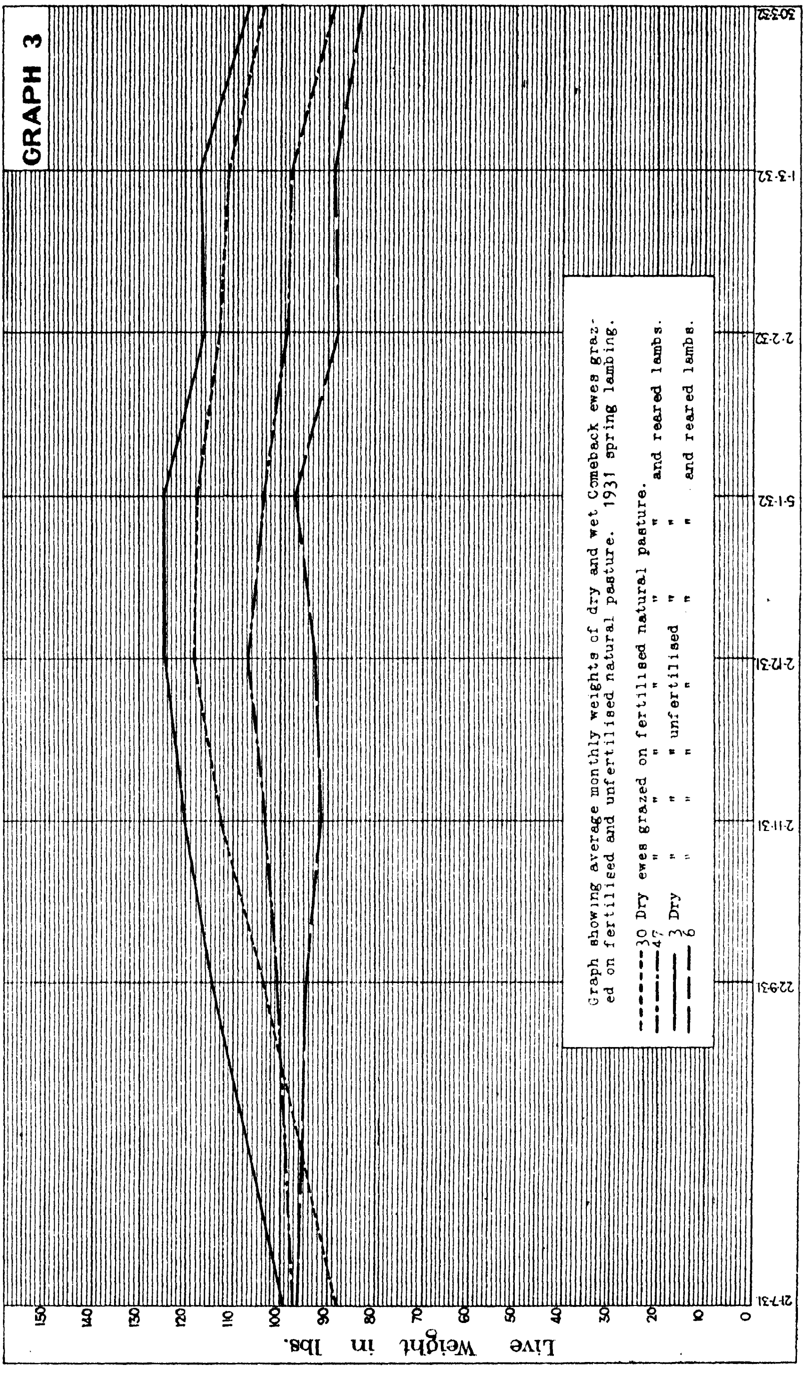
It is to be noted that since this experiment was commenced in 1929, only one loss of ewe has occurred; 1 young hogget died in Flock B during October, 1929; 2 lambs in B Flock, and 5 lambs in C Flock died between marking and weaning in 1930-31 season; whilst 1 lamb in A Flock and 2 lambs in B Flock died this last season, 1931-32. No other deaths have occurred amongst these flocks during the three seasons.

Considered on the whole, the land fertilised with lime as well as superphosphate shows to best advantage, with its high carrying capacity of 3.39 sheep per acre, combined with highest lambing percentage, above the average in weight of wool, and general good health of sheep.

The sheep have had no hand-feeding. They had a course of drenching for internal parasites during 1931, but have received no licks, and have therefore depended entirely on the pasture growths for their total food.

The general conclusions apparent on this class of pasture are that, in the virgin state it is not suitable for breeding sheep, but satisfactory for carrying store sheep, and producing good-quality wool. When improved with fertilisers the pastures become

GRAPH 3



Graph showing average monthly weights of dry and wet Comeback ewes grazed on fertilised and unfertilised natural pasture. 1931 spring lambing.

fair for breeding purposes, carry many more sheep, and although the quantity and quality of wool per head is not materially affected, the quantity per acre has been increased 18.67lbs. per annum, or 230 per cent., by manuring with lime and super., 16.70lbs., or 205 per cent., by manuring with superphosphate only, and 8.83lbs., or 109 per cent., by manuring with ground rock phosphate.

Sown Pastures: Subterranean Clover and Wimmera Rye Grass.

The 15 plots of this pasture mixture established during 1924 are being maintained, and fully grazed each season. This year they were again grazed in rotation, using 213 ewes (98 half-bred ewes, 65 Combeback ewes 1929 drop, and 50 Comeback ewes 1930 drop). They were proportionately divided into four flocks on the 65 acres of manured plots. There was a good carry-over of feed on the plots from the 1930-31 season, and grazing has been continuous on the plots for the whole season of 1931-32. There was a large growth of clover and annual grasses this season. Wimmera Rye grass was present, but in only small proportion.

Table 6 shows the fertiliser given to the various plots, with the rate and time of application, together with the grazing results for the past seven years.

In commenting on this table, it is to be noted that very high yields are continuing to be received. Plot No. 7, in carrying 5.47 sheep per acre, is the greatest received from any plot for the seven years of the experiment, and it is of particular note that this plot has been regularly improving each season, from 3 sheep per acre in 1925 to 5½ sheep per acre this year, giving an average carrying capacity over the seven seasons of 4.17 sheep. This plot has been fertilised with 1 ton lime per acre in 1924, and 1cwt. 45 per cent. super. each autumn since. Plot No. 3, fertilised with gypsum and super., was second this season with 5.18 sheep per acre, which is also the best return that this plot has given. The season with its quick finish undoubtedly gave these two plots an advantage, as the effect of lime and gypsum is to hasten early growth and quick maturity of plants. The three plots Nos. 4, 5, and 15, dressed with superphosphate, all yielded good returns this season of over 4½ sheep per acre. For the past four seasons Plot No. 5 has been dressed with 180lbs. 45 per cent. super. per acre per annum, and for the four years has carried an average of 4.95 sheep per acre. Plot No. 4, with 90lbs. super. per acre for the same period, has carried 4.40 sheep, and Plot No. 6, with 45lbs. super., has carried 2.85 sheep per acre. The check plot (no manure) has carried during these years 1.13 sheep, hence it is readily seen how responsive this pasture is to continued superphosphate dressings. The four plots are tabulated together as follows, showing yields of pasture, cost of fertiliser per acre and per sheep, and profit when sheep are valued at 10s. per annum.

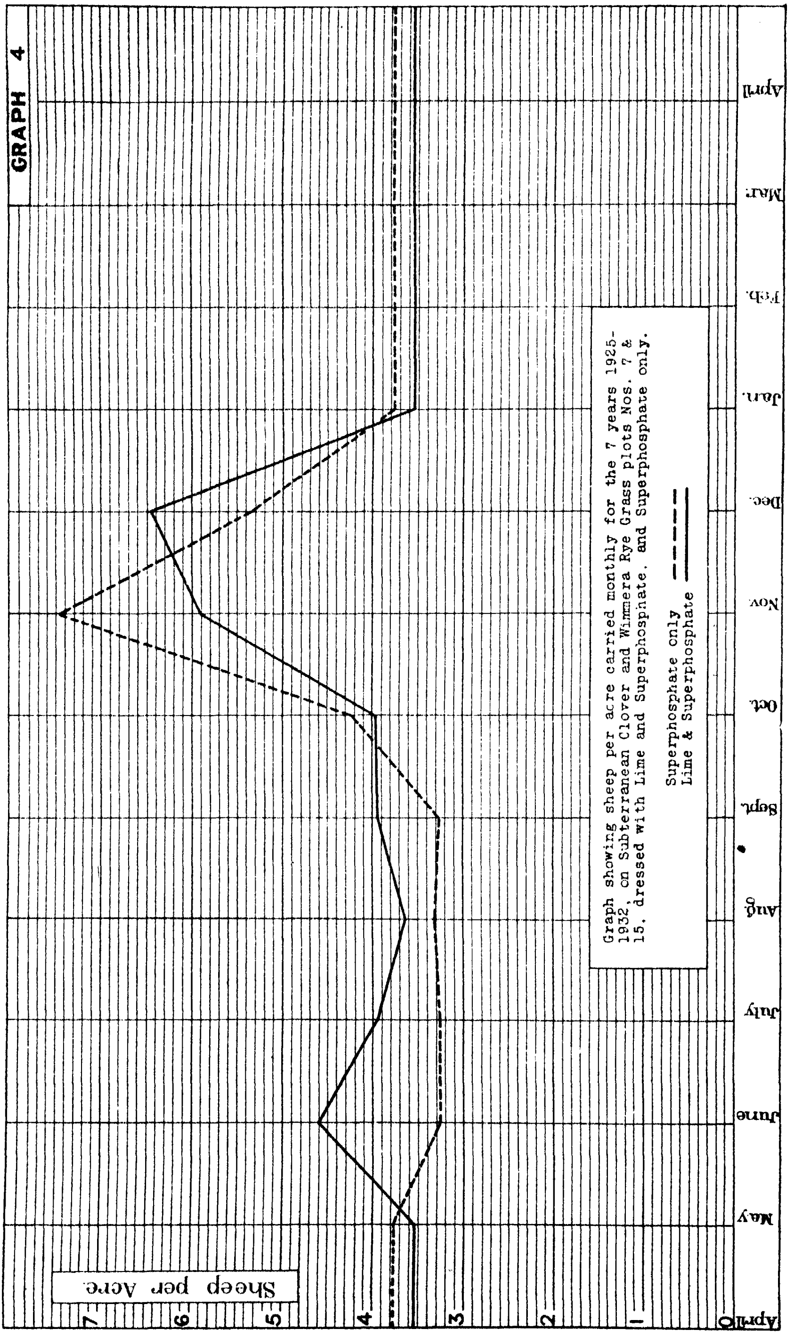
TABLE 7.—*Superphosphate Quantity Test on Subterranean Clover and Wimmera Rye Grass*, 1928-1931.

Plot.		Sheep Carried per Acre.	Increase over No Manure.	Cost of Fertiliser per Acre.	Cost of Fertiliser per Sheep.	Value of Increased Grazing at 10s. per Sheep.	Profit per Acre per Annum Due to Fertiliser.
				s. d.	*s. d.*	*s. d.*	*s. d.*
No. 5.	180lbs. super.	4·95	3·82	9 4	2 5	38 2	28 10
No. 4.	90lbs. super. ...	4·40	3·27	4 11	1 6	32 8	27 9
No. 6.	45lbs. super. ...	2·85	1·72	2 8	1 7	17 2	14 6
No. 9.	No Manure	1·13	—	—	—	—	—

These results are the average annual returns over a four-year period, and indicate the value to be obtained from the use of superphosphate on a sown pasture of Subterranean Clover and Rye grass, combined with systematic rotational grazing. For this grazing the fertilised plots have been fed off monthly in rotation with approximately 16 sheep per acre, whilst the unfertilised plot was grazed monthly with approximately three sheep per acre.

The attacks of the larvae of the cockchafer beetle during winter did not affect any of the plots this season, and consequently Plot No. 15, which is also fertilised with super., recovered well from the set-back it received in 1930-31.

Referring further to Table No. 6, the averages for the seven seasons show clearly that Lime and Superphosphate are the most productive of the fertilisers tried. The two combined have given the greatest yield, whilst superphosphate on its own has yielded almost as well in quantity of feed. Lime has an advantage, however, in producing quicker early feed, and more during the colder months of the year. Graph 4 shows the monthly grazings secured from Plots Nos. 7 and 15 during the seven seasons, and shows this advantage of lime in providing winter feed.



Graph showing sheep per acre carried monthly for the 7 years 1925-1932, on Subterranean Clover and Wimmera Rye Grass plots Nos. 7 & 15, dressed with Lime and Superphosphate, and Superphosphate only.

This graph shows the actual average monthly grazings taken from the two plots, and although they have been grazed to their full during the winter months, the flush growth of spring has not been completely used at that time of the year. It naturally has been necessary to allow this growth to mature to provide feed for late summer and autumn. The comparatively heavy grazings of October, November, and December are due to the allowance for lambs, which were dropped by the ewes on the plots during August, and weaned early in January. The graph shows that quite an appreciable increase of pasture has been received from the lime and super. plot during June, July, August, and September, whilst the autumn feed of January, February, March, and April has been greater on the super. only plot. This is apparently due to the greater proportion of clover in the super. only pasture, providing more clover seed for stock at this period.

Plot No. 8 dressed with 6cwts. Ephos phosphate in 1924 has also yielded a high return of pasture—approximately four sheep per acre average. This pasture has not given such good winter feed as lime and super. plot, but has maintained a high content of clover.

The average results of the principal plots for the past four years are compared below in order of productivity.

TABLE 8.

Kind and Rate of Fertiliser.	Annual Cost of Fertiliser.	Increase above No Manure. Sheep per Acre Carried.	Sheep. per Acre.	Percentage.	Value at 10s. per Sheep.	Profit per Acre per Annum Due to Fertiliser.
	s. d.	%	%		s. d.	s. d.
1. Annual dressing 180lbs. 45% super.	9 4	4·95	3·82	338	38 2	28 10
2. Single dressing 1 ton Lime and Annual dressing 1cwt. 45% Super.	11 0	4·80	3·67	325	36 8	25 8
3. Single dressing 1 ton Gypsum and Annual dressing 1cwt. 45% Super.	10 9	4·66	3·53	312	35 4	24 7
4. Annual dressing 90lbs. 45% Super.	4 11	4·40	3·27	289	32 8	27 9
5. Single dressing 6cwts. Ephos Phosphate	3 9	4·19	3·06	271	30 7	26 10
6. *Annual dressing 1cwt. 45% Super.	6 0	3·95	2·82	250	28 2	22 2
7. Dressing 4cwts. Rock Phosphate every five years and Annual dressing 37lbs. Potash	9 8	3·47	2·34	207	23 5	13 9
8. Single dressing 4cwts. Rock Phosphate and 1cwt. 45% Super.	2 9	3·24	2·11	187	21 1	18 4
9 Annual dressing 45lbs. 45% Super.	2 8	2·85	1·72	152	17 2	14 6
10. Dressing 4cwts. Rock Phosphate every five years	4 2	2·84	1·71	151	17 1	12 11
11. Annual dressing 37lbs. 90% Potash	5 6	2·22	1·09	96	10 11	5 5

*During 1930-31 this plot was badly affected by ravages of caterpillars.

From the above, it is apparent that, so far as quantity of production is concerned, the water soluble phosphates and lime are the most remunerative fertilisers to apply. They have yielded approximately 63 per cent. better than acid soluble phosphates. Potash fertiliser shows an increase of 96 per cent. over no manure, but when combined with acid soluble phosphate it gives only an increase of 22 per cent.

(To be continued.)

PROGRESS

If you contemplate the future, as we all can and do, you must gather some conception of the enormous progress that civilisation will inevitably make within the probable period of your life.

You must realise, too, that such progress will be the sum total of all individual endeavours. Thus you will realise, no doubt have already accepted, your own part in this great forward movement, which is progress. If you are to play your part valuably you must not be a drag upon any other section of the community, but, in one respect at least, you can provide against this.

The Savings Account will help you build your career, help you to independence, and therefore to a useful place as a citizen. Very little money is required to start an account, which will cost you only the decision to open it, and to faithfully maintain it for your own, and, therefore, for the general national welfare.

WHEAT VARIETIES IN SOUTH AUSTRALIA.

[By R. C. Scott, R.D.A., Supervisor of Experimental Work.]

(Paper read at the Forty-third Congress of the Agricultural Bureau, September, 1932.)

Since wheat was first planted in South Australia some hundred years ago, much has been done in the development of varieties specially suited to the soil and climatic conditions obtaining in the State.

The difficulty encountered by the early wheat farmers was that although numerous varieties were imported from overseas not one was found to be well suited to the stringencies of the climate. The chief faults of the imported wheats appear to have been their lateness in maturing, their lack of resistance to early summer drought, and their liability to attack by red rust. Consequently, whilst in favorable seasons satisfactory yields were harvested, on the average the returns were very disappointing.

It was therefore evident that special types would have to be evolved if the State were to make progress in wheat production. In this connection we owe a debt of gratitude to such men as Messrs. J. Ward, Port Pirie; H. J. Gluyas, Port Germein; R. Marshall, Wasleys; J. King, Georgetown; D. Leak, Second Valley, and a number of others who in the early days isolated and built up improved strains of wheat.

In fact, several of the varieties selected by these men are still being successfully grown to-day whilst practically all have been used as parents in the production of our best wheats.

HISTORY OF WHEAT VARIETIES.

In view of the importance of the wheat industry in South Australia and the part which the foundation wheats have played in its development a few notes regarding the history of varieties may be of interest.

The early records indicate that toward the middle of last century Red Straw, Club Head, Brodies, and Goldsmith were the varieties commonly grown. No mention is made of their origin, but they were probably imported from England.

In the sixties red rust was particularly severe and wheat crops were badly affected. However, farmers had no opportunity of securing more resistant types, and 25 years later Red Straw and Club Head were still being largely grown, whilst Purple Straw and Talavera had taken the places of Brodies and Goldsmith.

This unsatisfactory state of affairs continued for some years, and despite the importation of wheats from overseas very little headway was made.

The turning point appears to have been the selection of Ward's Prolific by Mr. J. Ward of Port Pirie in 1881, and since that time there has been steady improvement in the disease and drought resisting qualities of the varieties available for planting.

In the early reports of the Department of Agriculture published by Professor Custance in 1882 to 1887, mention is made of the fact that hot winds of early summer consistently affected the majority of wheat varieties and often completely ruined many of those imported from England. Professor Custance added that as the result of these tests which embraced 46 varieties and included the recognised South Australian wheats, together with importations from England, India, South Africa, and New Zealand, he was certain that an early ripening type was necessary for maximum yields under local conditions.

The most promising wheats in these experiments were Early Baart, Purple Straw, and Ward's Prolific. It is interesting to note that from these three wheats many of the best varieties grown in the Commonwealth have been derived.

During the next few years there was considerable improvement in the quality of the wheats available for planting. The more important types developed before the end of the century were Early Gluyas, Marshall's No. 3, King's Early, Carmichael's Eclipse, Steinwedel, Leak's Rust Proof, Baroota Wonder, and Early Para. There were, of course, many other varieties being seeded, over a hundred in all being listed in the State, but those mentioned were the most popular. Early Baart and Purple Straw lost favor, but Ward's Prolific retained its position, although it appears to have been somewhat unfixed in type, as a number of selections were made from it, including Early Gluyas, Marshall's No. 3, Carmichael's Eclipse, and Baroota Wonder.

From 1900 onwards the influence of the plant breeding stations situated in the different States began to be felt.

New crossbred wheats were built up and distributed throughout the Commonwealth. At Roseworthy Agricultural College organised selection and wheat breeding work was commenced, whilst Mr. R. Marshall, of Wasleys, who had long been experimenting with varieties, was successful in evolving new wheats of considerable value.

The position regarding suitable varieties was, therefore, very much improved, and farmers could secure types able to respond under the particular conditions in which they happened to be working.

The principal new wheats were Federation, Yandilla King, Late Gluyas, King's White, and German Wonder, whilst during the past 10 years or so Queen Fan, Caliph, Currawa, Ford, Daphne, Sultan, Felix, Gallipoli, Waratah, and Nabawa have come into prominence. These represent the wheat varieties which have been extensively seeded throughout the period of wheat production in South Australia, and we can now proceed to briefly outline their origin and principal characteristics.

Origin and Principal Characteristics of the More Important Wheats.

Early Baart.—A bearded early-ripening wheat imported into South Australia from Cape Colony about 1880. Because of its early maturing properties it tended to escape the attacks of red rust and also ripen its grain before the hot weather of summer was experienced.

Purple Straw.—Imported into New South Wales from California in 1851, and some 10 years later introduced into this State, where it became very popular because of its drought-resistance. It is one of the parents of Federation.

Ward's Prolific.—The result of a selection made by Mr. J. Ward, of Nelshaby, Port Pirie. In 1880 Dr. Schomburgk imported a number of wheat varieties from overseas and distributed them amongst farmers. Samples were forwarded to Mr. Ward for trial, and in the second year he noticed a single rust free plant in the plot of Du Toit's wheat. The remaining plants were badly infected.

The grain from the rust-free plant was harvested separately and formed the starting point of Ward's Prolific variety. It retained a certain degree of rust resistance, and also yielded well under low rainfall conditions, with the result that it soon became the most widely cultivated wheat in South Australia.

Early Gluyas.—This wheat owes its origin to the work of Mr. H. J. Gluyas, of Port Germein. In 1894 Mr. Gluyas selected eight or nine strains from Ward's Prolific, finally retaining two which exhibited marked drought and disease resistance. These he named Early Gluyas and Gluyas Dark Straw. The latter has now gone out of cultivation, but in the opinion of Farrer was identical with the wheat known as Wilkinson. Early Gluyas possesses characteristics which may be regarded as typical of a drought resistant wheat for South Australian conditions, namely, relatively sparse stooling habits, fine willowy straw, and a minimum amount of flag coupled with resistance to rust and early maturing qualities.

Marshall's No. 3.—Was raised by Mr. R. Marshall, of Wasleys, in 1890, when he selected a white chaffed wheat with purple straw from a crop of Ward's Prolific.

In subsequent cultivation both purple and white strawed plants were produced and by further selection Mr. Marshall succeeded in fixing both types. The former he named Marshall's No. 3, and the latter Silver King.

King's Early.—A selection from a crop of Early Baart made by Mr. Joseph King, of Georgetown. The distinguishing features were earliness in ripening and solidity of straw. This wheat yielded both red and white colored grain. Later on the colors were separated at Roseworthy Agricultural College to form two distinct varieties, namely, King's Red and King's White.

Carmichael's Eclipse.—A bold eared velvet chaffed wheat raised by Messrs. Carmichael Bros., of Telowie. Is probably a selection from Ward's Prolific, although the variety has been claimed to be a cross between Ward's Prolific and Velvet Pearl.

Steinwedel.—This is one of the earliest wheats in the State, originating about the same time as Ward's Prolific. It was selected from a crop of Farmer's Friend by Mr. A. Steinwedel, of Balaklava. It proved very vigorous and prolific, but had the disadvantage of tending to badly shatter its grain.

Leak's Rust Proof.—A selection made by Mr. D. Leak, of Second Valley, about 1887. In a badly rusted crop of White Tuscan a single plant was found which was quite clean of disease. It had fine tough straw, but the ears were short and thin. The resulting variety proved distinctly rust resistant, whilst by selection the yielding ability and characteristics of the ear have been much improved.

Early Para.—This variety originated from a beardless plant found in a crop of African Bearded Wheat. It was built up by Mr. A. B. Robin, of Nuriootpa. For a time it was very popular, but was eventually discarded because of its weak straw.

Federation.—Was bred by William Farrer, of New South Wales, in 1895, who five years later forwarded grain of the new crossbred to Mr. F. Coleman, at Saddleworth. The results obtained were much superior to those secured from other varieties, and in the space of a few years large areas were placed under cultivation. This was not only the case in South Australia, but also throughout the Commonwealth generally, and the work of Farrer with this one variety alone has meant much increased wealth to Australia. The parents of Federation are Yandilla and Purple Straw.

Yandilla King.—This is probably the most successful variety produced by Mr. R. Marshall, of Wasleys, and is the result of crossing Yandilla with Silver King.

Late Gluyas.—A selection from Early Gluyas made at Roseworthy Agricultural College which ripens its grain a few days later than its parent. It also possesses stronger, stouter straw and bolder ears. Whilst not quite as hardy as Early Gluyas, it has proved a good wheat in those districts where, because of local conditions, the tendency for the latter to lodge is a serious defect.

King's White.—The strain of white colored grain isolated from King's Early at Roseworthy College.

German Wonder.—An earlier ripening selection from Marshall's No. 3 made by Mr. F. W. Schultz, of Pine Forest, about 1906.

Queen Fan.—A cross between Fan and Carmichael's Eclipse made at Roseworthy Agricultural College which showed high yielding ability, but, owing to its liability to disease, is now losing favor.

Caliph.—Another College crossbred wheat claiming King's White and Marshall's No. 3 as parents. It has proved a very satisfactory variety for the Mallee lands generally.

Currawa.—A relatively late maturing variety which has exhibited a fair amount of drought and rust resistance. It was bred by Mr H. Pye, at Dookie Agricultural College, Victoria, by crossing Northern Champion, Cretan, and Little Club.

Ford.—This wheat was bred at Roseworthy College, the pedigree being Fancy x Crossbred 52. It is very tolerant of soils containing excess lime and has proved of value in the fair quality Mallee lands.

"No fear of a Drought With a Metters about."

Sultan.—Sultan represents an attempt to breed a hay wheat yielding good quality solid straw similar in nature to King's White, but one in which the beard of King's had been eliminated. The work was done at Roseworthy by crossing King's White with Caliph, and therefore Sultan comprises three parts King's White blood and one part Marshall's No. 3.

However, whilst the development of a hay wheat was aimed at, a dual purpose variety was secured capable of producing good yields of both grain and hay, but one which is somewhat liable to red rust attack when the infestation occurs early in the season.

Felix.—This wheat is bred on somewhat similar lines to Sultan, being (King's White x Jonathan) x King's White. It is a relatively good grain and hay yielder, and has given satisfactory returns in many parts of the State.

Gallipoli.—Gallipoli and Free Gallipoli have the same origin, the latter being an easier threshing selection from the former. The earlier very tough threshing strain has now been practically discarded, and, therefore, at the present time the prefix "Free" is rarely used.

The parents of Gallipoli are Club Head and Yandilla King. The cross was made by Doctor A. E. V. Richardson, and the variety built up in Victoria.

It is best suited to the more fertile soils of the higher rainfall areas, but it is also markedly drought resistant and has done well in the Mallee lands generally. Gallipoli is the most widely grown wheat in Victoria.

Waratah.—This wheat is the chief variety in New South Wales, and is rapidly increasing in popularity in this State. It was bred in New South Wales by crossing Hudson's Early Purple Straw with Early Gluyas. It is a useful early maturing wheat for the medium rainfall districts.

Nabawa.—Particular atention has been drawn to this wheat in the last few seasons because of its ability to ripen its grain under the adverse finishing conditions which have been experienced. It is the result of a cross made in New South Wales between Gluyas and Bunyip, and the Nabawa strain originating from the crossbred was developed in Western Australia.

An outstanding feature of this wheat is its resistance to flagsmut whilst at the same time it is also fairly rust resistant. It has yielded extremely well in most parts of the State and risen to top position in the areas of varieties planted in both Western Australian and South Australia.

LEADING WHEAT VARIETIES PLANTED IN SOUTH AUSTRALIA.

During the past eight seasons the Government Statist has recorded the areas sown with different wheat varieties in this State. The relative positions of the 12 most extensively seeded varieties is shown in the following tables:—

AREAS (IN ACRES) OF LEADING VARIETIES OF WHEAT SEASONS, 1924–31.

	1924.	1925.	1926.	1927.	1928.	1929.	1930.	1931.
Nabawa	—	1,897	6,096	41,678	116,220	288,878	560,626	802,730
Early Gluyas	463,021	474,914	490,590	517,442	621,817	649,915	621,575	570,696
Late Gluyas	212,190	212,198	226,757	273,024	331,737	423,116	444,705	324,751
Federation	408,096	331,756	332,604	372,683	393,293	347,738	374,996	316,266
Gallipoli	—	1,261	3,589	16,621	39,581	72,520	183,280	234,891

Felix	27	25	20	17	14	12	10	11
Daphne	10	7	6	7	9	9	11	12

Reviewing both tables as a whole it will be seen that Nabawa is now the leading wheat, with a total area of 802,730 acres. This represents 18.55 per cent. of the total land seeded to wheat. The increase in popularity of Nabawa is somewhat remarkable, as in eight seasons it has multiplied from a very small plot to the area mentioned. With the exception of season 1931 Early Gluyas has headed the list on every occasion, and over an average of years must be regarded as our foremost variety. If the area is combined with that for Late Gluyas it is seen that these Gluyas strains have occupied upwards of a million acres, or about 25 per cent of the area planted with wheat in South Australia. Late Gluyas and Federation have retained their positions, although in both cases a smaller acreage was seeded than in the previous year. Gallipoli has jumped into prominence, and has moved up from sixty-first to fifth position in six years. Another wheat which has rapidly increased in popularity is Waratah. Very little of the variety was planted in 1925; in fact, the area was so small that it is not recorded, whilst it now holds eighth place with 141,934 acres. Ford reached its peak period in seasons 1926 and 1927 when it was the second most important wheat, totalling 12.27 and 12.87 per cent. of the area cultivated. However, since that time there has been a steady decline in the area seeded, and it now occupies seventh position, or approximately half the area of that seeded in 1927. Currawa, Sultan, Caliph, Felix, and Daphne have also slipped back in positions and acreages, and are being steadily displaced by other varieties.

In all rather more than 200 varieties are listed by the Government Statist, and, therefore, numerous types are being cultivated. However, the 12 leading wheats tabulated represent over 75 per cent. of the area of wheat seeded. Included in the remaining 25 per cent. are many useful older wheats, together with new varieties in the process of development, whilst about 4 per cent. of the total area comprises varieties whose names were not specified on the returns lodged.

Consequently from the point of view of the State, the area seeded with inferior varieties is not particularly important, but in the matter of individual farmers there are a number continuing to plant wheats which are out of date and which could be profitably replaced with improved types.

The only way in which the value of new crossbred or selected wheats can be ascertained is by submitting them to test in various districts under ordinary farming conditions. Therefore, no restriction on the number of varieties planted is suggested, but attention is drawn to the fact that we have too many old type wheats in cultivation which should be abandoned.

Many farmers are loth to discard wheats which have proved successful in the past, and whilst such caution is often justified, the testing from time to time of a new variety which has given satisfactory returns under similar agricultural conditions is to be recommended. The area seeded should not be large, but arranged according to the size of implements available and the convenience of harvesting.

It is obvious that if a variety can be secured which under the same conditions is a better yielder than other varieties, then the annual cash return is increased at practically no additional expense.

Choice of Varieties.

In the foregoing remarks the question of wheat varieties has been discussed in a general way. However, it is recognised that owing to the vastly different agricultural conditions under which wheat is planted in South Australia no single variety is likely to prove universally successful. Therefore, wheats possessing special characteristics must be seeded in different districts in order to give maximum returns under the particular soil and climatic conditions obtaining in each locality. Even on the same farm three or four varieties are usually planted so that the season's work may be distributed according to their rate of maturity.

In order to provide information on the value of different wheats 14 series of variety experiments, including those at Roseworthy Agricultural College, are being conducted by the Department of Agriculture in various parts of the State. As they have been in progress over a varying number of years, it is difficult to draw up a table in which the results from one series are strictly comparative with those from another. However, in the following tables an attempt has been made to group the centres according to their respective soil and climatic conditions, and from that point of view the State has been divided into six sections:—

Yields from Experimental Plots situated in Low Rainfall Districts and on Light Mallee Soils overlying a Well-drained Subsoil.

Veitch. (1922-28).		Sandalwood. (1928-31).		Copeville. (1929-31).		Coorabie (1929-31).	
Variety.	Bush.	Variety.	Bush.	Variety.	Bush.	Variety.	Bush.
Sultan	15·95	Gallipoli	14·00	Canberra	18·08	Daphne	10·73
Walker's Wonder	12·42	Nabawa	12·28	Faun	17·88	Sultan	9·45
Late Gluyas	12·35	Currawa	12·03	Regent	17·15	Canberra	9·00
President	11·70	Gluyas	10·82	Gluyas	16·72	Faun	8·55
Yandilla King	11·35	Yandilla King	10·68	Gallipoli	16·17	Felix	8·00
Baroota Wonder	11·05	Caliph	10·50	Felix	15·92	Gluyas	5·90

The same wheats are not represented in each test, but from the results obtained it would appear that Sultan, Gallipoli, Canberra, Daphne, Nabawa, and Gluyas can be recommended for planting under such conditions. Canberra is an early-maturing Federation crossbred which is able to develop its grain under adverse ripening conditions, and, although susceptible to flag smut, has yielded well on northern Eyre Peninsula.

Yields from Experimental Plots situated in Low Rainfall Districts (under 15in.) and on Light Mallee Soils overlying a Fairly Retentive Subsoil.

Minnipa. (1923-29).		Yurgo. (1928-31).		Kimba. (1927-31).		Rudall. (1927-31).	
Variety.	Bush.	Variety.	Bush.	Variety.	Bush.	Variety.	Bush.
Sultan	17·92	Nabawa	20·18	Gluyas	13·58	Gluyas	12·10
Felix	17·35	Gluford	19·07	Caliph	12·12	Caliph	11·57
Canberra	17·35	Currawa	18·85	Sultan	11·87	Faun	11·48
Faun	17·33	Caliph	18·67	Federation	10·17	Sultan	10·27
Gluyas	17·17	Baldmin	18·02	Ford	9·52		
President	17·17			Currawa	8·45		

In these series Early Gluyas has headed the yields at two centres and maintained its reputation as a very hardy variety. Sultan and Nabawa have also given satisfactory returns, whilst Caliph is well up in the averages.

These four varieties may be regarded as the most valuable wheats for these districts.

YIELDS FROM EXPERIMENTAL PLOTS SITUATED IN LOW RAINFALL DISTRICTS (UNDER 15IN.) AND ON LAND OF RELATIVELY HEAVY NATURE OVERLYING A RETENTIVE SUBSOIL.

Cortlinye. (1928-31).		Brownlow. (1930-31).	
Variety.	Bush.	Variety.	Bush.
Caliph	5·25	Nabawa	8·55
Gluyas	5·02	Begum	7·97
Felix	4·95	Canberra	7·05
Federation	4·80	Sultan	6·93
Yandilla King	4·60	Federation	6·40
Ford	4·35	Gluyas	6·28

Wheat growing under these conditions of soil and moisture is attended with considerable risk, and as far as the Cortlinye plots are concerned a complete failure is recorded for 1929, whilst extremely poor crops were harvested in both 1928 and 1930.

In good seasons high yields are secured from such wheats as Federation and Yandilla King, but on the average the earlier ripening types are to be preferred. From the limited results available no recommendations can be made, but probably Caliph, Nabawa, Gluyas, or Canberra will prove the most valuable varieties.

YIELDS FROM EXPERIMENTAL PLOTS SITUATED IN MEDIUM RAINFALL DISTRICTS (15 TO 17IN.) AND ON LAND TYPICAL OF BETTER QUALITY MALLEE COUNTRY.

Roseworthy College. (1927-31).		Urania. (1929-31).	
Variety.	Bush.	Variety.	Bush.
Sword	21·45	Nawab	25·22
Nawab	19·83	Sword	24·85
Dawn	18·32	Nabawa	24·80
Gluyas	18·32	Caliph	24·03
Regent	18·32	Sultan	23·90
King's White	18·25	Begum	23·17

In these experiments a number of new wheats have been submitted for trial, and it will be noted that two comparatively unknown varieties occupy first and second positions at each centre. These are two very promising wheats well worth testing under conditions similar to those at these centres.

Both were bred at Roseworthy College, Sword being obtained by crossing Sultan with Ford, whilst Nawab claims Anvil (King's White x Jonathan) and Sultan as parents. They are both beardless, white chaffed, relatively drought resistant varieties which are able to thrive in the limestone soils of this State.

Nabawa is not listed amongst the Roseworthy tests, whilst at Urania Ford was omitted in one season, and therefore cannot be included in the averages. However, our knowledge is such that we could recommend both Nabawa and Ford, together with Caliph, for similar districts, whilst Sword and Nawab appear likely to prove at least equal, if not superior, to the varieties mentioned.

YIELDS FROM EXPERIMENTAL PLOTS SITUATED IN GOOD RAINFALL DISTRICTS (17 TO 18IN.) AND ON FERTILE LAND OF THE RED BROWN EARTH CLASS.

Booborowie. (1924–29).		Ungarra. (1927–31).	
Variety.	Bush.	Variety.	Bush.
Merredin	24·28	Faun	28·35
Federation	23·98	Sultan	27·55
Dan	23·47	Gluyas	27·28
Nabawa	21·98	Caliph	27·12
Caliph	21·45	Currawa	26·25
Carrabin	20 90	Ford	25·50

On account of the closing of the Booborowie Experimental Farm no results are available beyond 1929. At that time Gallipoli had only recently been included in the variety trials. At Ungarra it has been tested for two seasons, and in this period has averaged 51lbs. per acre more than Faun, which is shown as the leading wheat.

The highest mean yield at Booborowie was obtained from Merredin, a Federation-Gluyas crossbred that originated in Western Australia. The most prolific wheat in the Ungarra trials was Faun, which was bred at Roseworthy Agricultural College by crossing Late Gluyas with Anvil.

Wheats which may be recommended for this country are Gallipoli, Merredin, and Federation, whilst for later planting Faun, Sultan, and Nabawa would be suitable.

YIELDS FROM EXPERIMENTAL PLOTS SITUATED IN HIGH RAINFALL DISTRICTS (18–20IN.) AND ON FERTILE LAND.

Keith. (1928–31). Variety.	Bush.
Bena	22·07
Sultan	20·62
Federation	18·40
Major	18·20
Dan	17·78

There are not many plots situated on this class of country typical of parts of the Lower North and the Upper South-East of this State.

At present only one series is in progress, namely, those at Keith. Work was commenced at Wolseley with Gallipoli, Federation, Wannon, Bena, Sepoy, Nizam, and Baldwin varieties, but last season the farmer with whom the Department was co-operating was unable to continue the experiment, and consequently no results are available.

Under the conditions obtaining in these districts the wheats seeded must have high yielding qualifications and ability to take advantage of the favorable opportunities offered. In this connection the best wheats appear to be Gallipoli, Wannon, and Federation.

The final division of the State, so far as wheat varieties are concerned, is that relating to those districts receiving a very high rainfall (25in. to 30in. per annum), and where the crop is planted on heavy fertile land. Areas of this nature are to be found in the Lower South-East.

In this locality Major and Crossbred 53 are the principal wheats at the present time, but a small trial is in progress at Millicent, where varieties imported from New Zealand are being planted.

It was considered possible that the types found more satisfactory in the cooler, wetter countries would prove superior to those developed principally for warmer, dryer climates. Consequently, Hunters, Velvet Chaff, and Hard Straw Tuscan were obtained and are now being tested in comparison with Major.

A summary of the position, so far as choice of varieties is concerned, is as follows:—

Gallipoli.—Is well able to adapt itself to a great variety of soil and rainfall conditions. It has high yielding ability, and is able to respond to favorable circumstances. At the same time it is tolerant of light mallee soil and highly resistant to drought.

Nabawa.—Can be generally recommended for our medium to light rainfall country. It possesses the advantage of being resistant to flagsmut and able to ripen grain of good quality under adverse conditions.

Early Gluyas.—Retains its position as the most drought resistant variety. Bearing in mind its relative weakness of straw, Early Gluyas can be recommended for the lower rainfall areas generally.

Sultan.—This variety develops freely in light soils and those containing appreciable quantities of readily soluble lime. It is drought resistant, and is capable of producing high yields of either grain or hay. Whilst not resistant to red rust it usually escapes severe attack from this disease. A useful variety for the medium to light rainfall areas of the State.

Federation.—May still be regarded as the typical high yielding wheat for the good soil and high rainfall districts, particularly those in which steady ripening weather is regularly experienced.

MALTING BARLEY ON THE FARM AND IN THE MALT HOUSE.

[By A. G. Barrett (Barrett Bros. Pty. Ltd., Maltsters).]

(Paper read at the Forty-third Congress of the Agricultural Bureau, September, 1932.)

The object of this address is to describe some of the characteristics of malting Barley and to show how the malting process takes place.

I am not, therefore, going to deal with soil preparation, seed preparation, and the like, which are better dealt with by the experts of the Agricultural Department, but will start with a few remarks on the barley crop as it approaches ripeness.

As a result of the long experience of many observers, it has been remarked that it is unusual except in specially favorable circumstances to find that Barley of good malting quality is harvested from a crop of more than 25bush. per acre or thereabouts. The reason for this seems to be that a crop which yields heavily has been planted in very fertile soil containing an excess of nitrogen or other plant food, and as a result sends up so many stalks that the moisture in the soil during the ripening period is not sufficient to fill out the grains which remain pinched. These grains will all grow if they are allowed to ripen properly, but they are useless to the maltster, as the nitrogen content of such a sample is usually too high in addition, and he is unable to obtain a malt that will be economical to his customers or to himself.

The nitrogen in barley all comes from the soil through the roots, but the starch or flour is developed from the green flag, and often in a pinched grain the roots have delivered to the ear all the nitrogen they can absorb, and deliver it early in the ripening process, whereas the starch is developed later and cannot be formed if the moisture in the soil fails.

Pinched grain, therefore, is not only uneconomical but usually has an abnormal proportion of nitrogen to starch which cannot be properly dealt with. It follows that at least in the central districts of South Australia barley should not be planted on fallow or on ground which is heavily manured. To do so is to risk failure as regards quality. A seven or eight bag crop can be expected to produce quality grain if it has a September rain to bring the ear well up from the flag and a rain in late October to keep the moisture supply going until the last moment and so fill the grain out properly.

Some damage occurs to the quality of barley if hot winds sweep the crop in October or early November, mainly because such winds shrivel the plants growing in bad soil patches and deprive the ear of its normal moisture. It is a very severe wind, however, which will seriously affect barley growing on good soil, as the roots of such plants can usually pick up enough moisture to repair any temporary drying of the plant. It is my opinion that too little attention is paid by farmers to the types of ground in a paddock, and it is rare indeed for paddocks to be divided up in accordance with the nature of the soil or the lay of the ground. Stony rises are sown and reaped together with flats, grey soil with red, and so on, and the result is that patches of crop damaged by hot winds or burnt by over-rich soil are harvested without any separation whatever and the good quality grain mixed with pinched grain. It follows that buyers will value such a sample at lower prices than a sample which is plump and regular, and in the long run a farmer will average more if he sells a patchy crop in two lots, one of good grain, and the other of pinched. In addition he is practically certain of a sale for the good portion, whereas with an irregular sample he may have the whole of it left on his hands for months, or at best store the line with a merchant for a small advance until it can be disposed of.

The factor which raises the price of a sample of barley above that of feed is its malting quality, and only by consistent attention to marketing the grain in the best possible condition can growers expect to capture the attention of buyers, especially overseas buyers, and raise the prices obtained.

Exporters of barley have the whole world to compete with, and farmers must realise that quality gets the high prices and neither Empire sentiment nor hard luck stories will induce a buyer to pay one penny more than a sample is worth.

Malted barley is used mainly for the production of beer, whisky, gin, vinegar, malt extract, yeast; and certain bakers' products and different samples are required for each; it is impossible to explain how one recognises each type, and it is only long experience which enables a maltster to select the proper line for each purpose. No chemical formula has yet been devised which will satisfactorily replace visual judgment. You may realise, therefore, that differences of selection between buyers may be explained by differing requirements, as well as by the mistakes we all make at times.

Although I cannot explain how to judge quality, I can explain the structure of good quality barley and how the grain is treated in the process of malting, and I will commence by describing a grain and its make-up with the help of

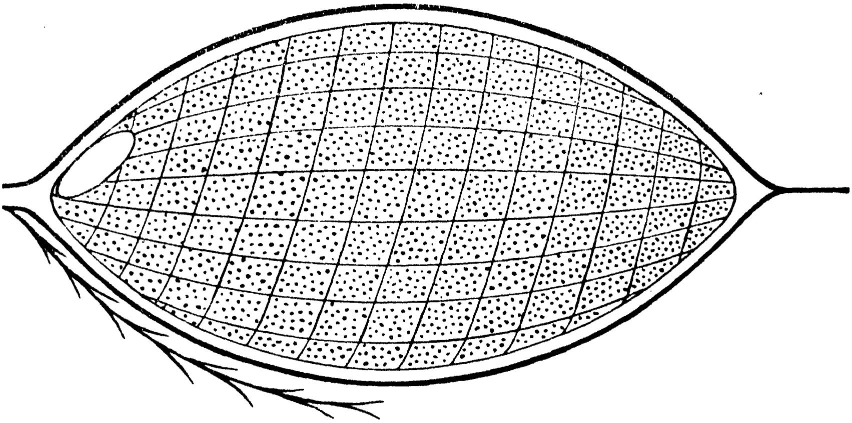

Diagram No. 1.

Diagram No. 1. The husk of barley is in two main parts, the section which covers the back of the grain overlaps the section covering the belly, leaving a passage at the germ end through which the roots protrude at the start of germination. The top half is prolonged at the other end to form the beard. Lying in the crease is a small fibre called the basal bristle, which, however, seems to have no useful purpose and is easily broken off. Underneath the husk is a complete envelope which encircles the germ and the grain proper. This is called the Testa, and it is of such fine texture that it allows nothing denser than water to pass it, and it filters out even matter dissolved in water. This skin keeps the interior of the berry secure from the attack of mould and bacteria, and allows the earliest growth to start with only the materials provided by Nature with, of course, the addition of pure water. Under the testa lies the germ, which is pressed down on the body of the grain but is not attached to it. The body of the grain is merely a storehouse of food for the germ, and supplies the energy necessary to enable the roots and leaf of the growing germ to increase enough to absorb their own sustenance from the soil and air. In malting the growing process is stopped after a certain stage is reached and before much of the food supply of the grain has been used up.

This food is starch and a mixture of gelatine—like substances called albumens. The starch is contained in minute paper—like sacs arranged in the manner of a honeycomb, and the whole of this portion is impregnated with the albumens. The chief object of the maltster is to dissolve the sacs enclosing the starch granules and to alter the albumens, making some of them soluble in water, some nearly soluble, and to leave untouched the remainder.

In the ripe grain just underneath the germ a small layer of ready formed plant food is provided which enables the germ to commence growth when sufficient water has been absorbed. Directly this process commences the germ secretes two main types of matter which attack and dissolve the albumens and the starch enclosing sacs. These two substances diffuse slowly until they have travelled the whole length of the grain, the inert albumens and the starch sacs being changed into soluble forms which become the food supply of the growing plant. In the paddock the whole of the grain is dissolved and made available to the growing roots and leaf, and only the husk remains. In malting, however, it is necessary to retain as much as possible of the starch, and it is not economical to use more than about 15 per cent. of the dry substance of the grain. After cleaning and grading a line of barley, it is soaked in water until it is soft, a process which takes from 30 to 60 hours, according to the season of the year; the water has to be changed frequently to prevent putrefaction and also to enable the grain to be aerated, as it is necessary for the germ to breathe air in order to keep it alive.

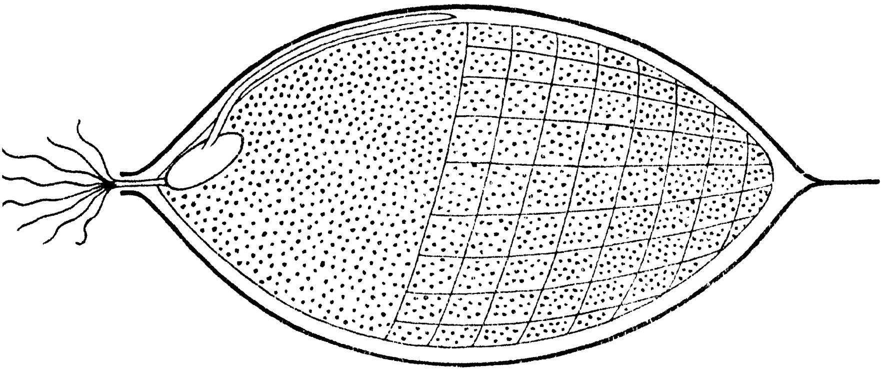

Diagram No. 2.

The soaked and swollen barley is then dropped on to growing floors and allowed to rest in fairly thick layers until the roots protrude. These burst through the fine underskin and follow the channel provided by the junction of the upper and lower husks. Most of the water absorbed by the grain in soaking enters through this same channel. Shortly after the roots show up, the first stalk of the plant commences to grow out of the germ. This also bursts through the underskin and grows up between it and the husk. As growth proceeds the change in the structure of the grain commences, and after three or four days portions of the berry are dissolved as shown in Diagram No. 2. You will see that the paper-like sacs nearest the germ have disappeared leaving the starch granules free to be acted upon by another substance which is formed as time goes on. This substance is called diastase, and its formation and regulation is the crux of the malting process.

It cannot be shown in the diagram, but at the same time the albumens are being changed into soluble forms, and the whole of the products of the gradually dissolving berry pass into the germ and are used by it to form the roots and leaf or stalk. At this stage the stalk has grown about half way along the grain and about five roots have lengthened out from the germ. During the process of growth a good deal of water is used up and must be replaced by sprinkling from cans or hoses, and this water is taken into the grain by the roots, in the same way that they extract water from the soil after rain.

As the barley grows a good deal of heat is generated by the chemical processes which are going on inside the grain, and it is necessary to keep the heaps cool either by turning them over with shovels or by currents of cold air or both. The turning of the heaps stops the roots from matting and becoming interlocked into a solid mass. After six to nine days the growth stops on account of much of the water in the grain having been used up, the roots wither, and the stalk practically stops growing. Diagram No. 3 shows the state of the grain at this period. Six or seven roots have been formed, the stalk has reached nearly the end of the berry, and all the paper-like sacs have been dissolved away, leaving the starch loose and free. From 30 to 40 per cent. of the original albumens have been rendered soluble or semi-soluble and the moist white portion of the grain is in a mealy condition instead of the elastic rubbery state it was in before growth started. The heaps of green malt are then loaded on to kilns and dried with hot air. The drying heats are arranged to add the required aroma, flavor, and color to the malt, and these qualities in malt made for brewing are imparted to the beer.

There are several different types of substances formed from the albumen of barley, all of which affect the products which are made from malt. The color and aroma referred to come from the albumens, as does the food for the yeast employed in fermentation, but perhaps the most important is diastase, which I mentioned a little while back. It is this substance which transforms the starch of the grain into sugary matter which can be fermented by yeast, and one of the major objects of the malting process has been to create diastase in the malt and to remove the paper-like sacs which would prevent the starch they contain being dissolved by the diastase. When the malt is dried on the kiln the husk of the grain has become merely a container of diastase, starch, and soluble albumens which later are put to their final uses in the brewery, malt extract works, or elsewhere. So far we have dealt with a perfect grain, but it should be realised that different seasons bring different qualities of barley and different problems for the maltster. South Australian barley is esteemed in England mainly because it is sun-ripened and so provides a type of malt which replaces certain deficiencies in the European types, which are usually harvested in wet weather.

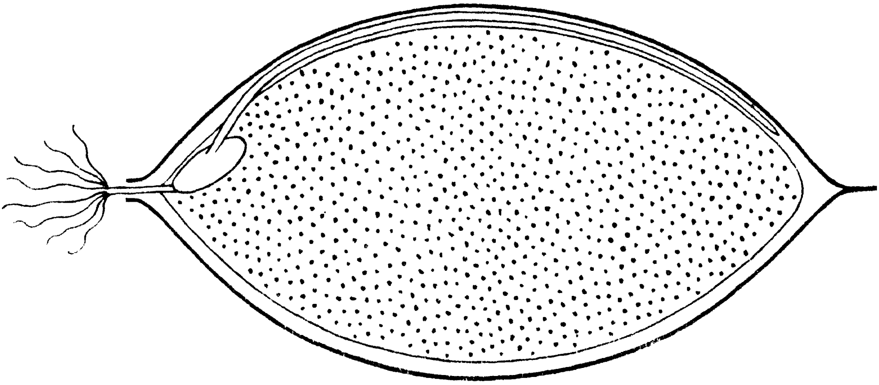

Diagram No. 3.

If our barley is properly treated by the grower every grain of it will grow, and this is its great attraction overseas. This phase of production has been neglected by many growers, and I have no hesitation in giving my opinion that when growers deliver to exporters and local users barley in the best possible condition they will average at least 6d. per bushel more as compared with grain marketed as it is now. The practice of delivering inferior barley even in small quantities and having it accepted by an agent either by bullying or trickery has cost the local farmer many thousands of pounds. It must be realised that every bag of barley is opened separately and a user soon knows where he is to look to find faults. There are some districts in South Australia from which I will not buy direct as I know I will be taken down, and some farmers from whom I will not buy for the same reason. When inferior barley gets into a large stack it is almost impossible to successfully remove it, if only on account of cost, and when say, an overseas user opens bag after bag of pinched or damaged grain he will avoid the risk of making similar purchases again, or if he does, only at a price far below the true value of the line to protect himself against further inferior deliveries. The English barley market has been practically closed to Australia on account of careless marketing, and it is only the improvement in the last couple of years that is drawing English attention again. The qualities which go to make a good sample and which are in the control of the farmer are fairly well known, and the first of them is the ripeness of the grain. Barley needs complete ripeness to allow it to grow and behave at its best, unripeness leads to uneven germination and inferior malt. If green patches are cut in an otherwise ripe crop sweating and heating may take place, and this will nearly always destroy the life of the grain and reduce its value to that of feed. Any suggestion of heating is regarded as suspicious by a maltster, who will never take a risk about barley which may not grow properly. Similarly, barley which has been badly wetted will grow unevenly and produce poor malt. Crops, therefore, should not be harvested until they are ripe, and the bags of barley should not be put on damp soil nor left in the paddock longer than necessary.

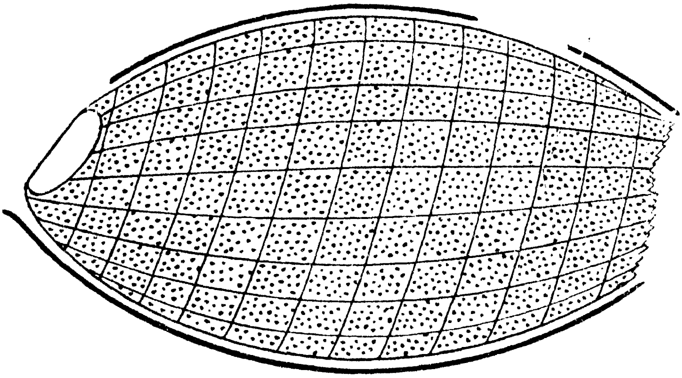

Diagram No. 4.

If lines cannot be carted promptly they should be stacked on dunnage and sewn. The filled sacks should be turned after rain several times, as otherwise the sewn end may become damaged after the bags have been up-ended. If barley has to be stored it should be in as airy a store as possible, as when it is stored in a close atmosphere weevil develops rapidly, does immense damage, and causes great loss of weight. New sacks should always be used, as second-hands rarely stand stacking and transport, with waste as a result, and in addition, they convey weevil to the stacks, with often disastrous results.

Anything which induces uneven germination depreciates the value of a sample, and in addition to the tendency to cut barley before it is ripe, a great cause of irregularity lies in the damage grain is carelessly subjected to during harvesting.

"WATTLE" Binder Twine

MADE IN SOUTH AUSTRALIA

"Good Twine Saves Time"

Farmers who insist upon a QUALITY Twine (keeping one eye on economy) should order "Wattle" brand this season.

"Wattle" brand has established a reputation for quality. Its unusual strength ensures freedom from breakages, it runs freely and evenly, thereby saving time and money.

"WATTLE"

SUPPLIES OBTAINABLE FROM ALL DISTRIBUTORS.

I have already explained how germination proceeds, and I will now show, with the aid of Diagram No. 4, how damage affects growth. You will recollect that the underskin is impervious to anything but pure water, and that most of the water absorbed by the grain in the first stage of malting enters by the channel formed by the junction of the two sections of husk. It can be seen, therefore, that in perfect grains the entrance for water is roughly the same size, and as a matter of fact the water spreads between the husk and underskin and passes into the berry over its whole length, both ends becoming soft more or less at the same time. But if some of the husk is removed during harvesting the entry for water is much enlarged, and a damaged berry will absorb much more water in the same time than a perfect grain. In a bad case the grain will become water-logged and die, or if not, will grow in a different manner from the bulk of the line and make irregular and therefore inferior malt, as the growth of the damaged grains cannot be controlled. If, in addition to the husk, the underskin is broken, the risk becomes greater, and such grains are nearly always killed by drowning. When a grain is broken or severely skinned, the interior is deprived of its natural protection and moulds and bacteria attack it, putrefaction sets in and imparts undesirable characteristics to the grain, especially as to flavor and aroma, which become very pronounced in beer and other products, the result being that people refuse to buy them. Hence mouldy malt cannot be sold, and maltsters will not buy broken barley which always carries the risk of mould. You will see too that if a grain will not grow it cannot be made into malt, and remains unchanged through the process. This, both economically and for other reasons, is undesirable, and malt containing much dead grain cannot be sold. It often happens that the back of the barley is scraped between the beaters during harvesting, and if this causes damage to the germ the loss of value of a sample may be serious indeed. Where this occurs the remaining portion of the germ secretes its substances, but as there is no root nor leaf, all the plant food formed becomes available to moulds and bacteria, with the result that the grain goes rotten and contaminates the whole of the malt. Such malt cannot be sold, and therefore barley affected by this form of damage cannot be bought except at low prices for feed.

Owing to the variation in the type of machines used and the differing daily temperatures, farmers around Adelaide are unable to get perfectly harvested barley, and local maltsters have to cope with a few damaged grains in each sample, but if a line contains more than 5 per cent. of badly damaged stuff it is considered unsuitable for malting, and it has to be sold at lower prices for other purposes. English buyers require grain that is practically perfectly harvested.

A perfect sample is one which ripened on the straw, has been properly stored, and which is free from damaged corns. It must be plump, regular, and mealy, free from oats, wheat, seeds, or any other foreign matter. Grain which has a steely, hard, or transparent look is unsuitable for malting, and short, round corns are usually preferred to those which are long, flat, and without a pronounced belly. Samples for malting look best when they have about one thirty-second of an inch of head remaining on the grain, but if it is impossible to take all the beard off without skinning, leave a little beard and avoid damage. If a line is obviously pinched and unsuitable for malting, it is not necessary to harvest it so carefully as beards are not wanted in a feeding line. The highest prices paid for barley are paid for the malting lines, and if growers seize the present opportunity and market their grain in the condition desired by buyers, especially those overseas, they will add to the value of their crop and secure a constant market in Europe, where the value of South Australian barley is just being realised.

Should a grower be in doubt on any point or desire information at any time, an inquiry from one of the reputable buyers will always bring a valuable reply, and the exchange of knowledge cannot fail to raise the standard of quality of this very profitable product.

INSECTS OBSERVED ON CROPS IN SOUTH AUSTRALIA DURING THE PERIOD JUNE, 1930, TO JUNE, 1932.(1)

[By J. DAVIDSON, D.Sc., F.E.S. (Waite Agricultural Research Institute, University of Adelaide).]

1. CEREAL CROPS.

Larvae of the Noctuid moth (*Cirphis unipuncta Haw.*) caused damage to self-sown barley in a local area in the South-East, but did not spread to the adjoining cereal crop.

2. PASTURE AND FODDER CROPS.

The "Lucerne flea" (*Sminthurus viridis* L.) was generally active a month earlier in 1932, owing to the early autumn rains. The insect demands a high humidity in its surroundings, and the moisture in the surface soil is the most important factor affecting these conditions (*see* Davidson, J.: Australian Journ. Expt. Biol. and Med Sci. 1932, Vol. X, pp. 1-16). Certain of the eggs remain viable in the dry surface soil during the summer months and hatch in autumn when the temperature and soil moisture are favorable (*see* Davidson, J.: Australian Journ. Expt. Biol. and Med. Sci. 1932, Vol. X., pp. 65-88). In the Adelaide hills district, in low-lying damp areas, active individuals may be noted until December. In similar situations the over-summering eggs were hatching out towards the end of February in 1932. Lime sulphur—1gall. in 60galls. of water—is an effective spray. The crop should be cut short or close-grazed before treatment. The first application should be given three to four weeks after the insects commence to hatch in the autumn, before they lay eggs. This will reduce the numbers in the next brood.

Certain of the reclaimed swamp areas on the River Murray were inundated by flood waters for several weeks during 1931. As a result, these areas had to be replanted after the floodwaters were pumped out. In one area which was replanted with lucerne in November, 1931, after being inundated from September 3rd, 1931, to the end of October, *S. viridis* was abundant in the crop by April, 1932. In certain other areas which had been submerged for longer periods, a few of the insects were observed in the new crops the following July. In every case the areas concerned had been infested with the insect prior to the floods. These observations indicate that certain of the eggs can withstand immersion for long periods, which is supported by the following experiment. On July 27th, 1932, a number of egg batches (estimated at about 10,000 eggs) laid on soil during the previous 14 days, were covered with about 6in. of water and left in the insectary. The eggs were in various stages of development. A number of the eggs hatched during the first two or three days, and the young insects floated up to the surface of the water. On September 7th, after being submerged for six weeks, the remaining water was poured off and the soil allowed to dry. A number of young individuals hatched out during the next few days, showing that eggs which had undergone considerable development survived the long period of immersion.

Weekly counts of the population of *S. viridis* in a plot of infested lucerne (about 1¼ acres) at the Waite Institute were made during 1932. On April 29th the total number of individuals in an area consisting of three samples (each sample 6½in. diam.) was 926. On May 20th, when a new generation was hatching out, it was 2,413. An account of these experiments will be published later.

Certain other species of Collembola occurred sparingly in the samples, notably *Isotomurus palustris* Mull. and *Katianna australis* Womersley (2)

A Bdellid mite (*Scirus longirostris*) occurred sparingly. It is of interest to note that Newman and Womersley (Journ. Agric. Western Australia, 1932, Vol. IX., No. 2) refer to another Bdellid mite (*Biscirus lapidarius*) as an active predator on *S. viridis.*

---

(1) The first records were published in this Journal, 1931, Vol. 34, pp. 741-745.

(2) I am indebted to Mr. H. Womersley for identification of the Collembola and mites recorded in this paper.

The red-legged mite of Western Australia (*Halotydaeus destructor* Tucker) and the red-legged or blue oat mite of Eastern areas of Australia (*Penthaleus bicolor* Froggatt) also occurred sparingly in the crop.

3. Field and Market Garden Crops.

The potato moth (*Phthorimaea operculella* Zeller) caused damage to tomato plants in a glasshouse near Adelaide in June, 1931. The eggs are laid on the leaves and the caterpillar burrows down the stem. Removal of affected plants is necessary.

Young onion plants in two gardens on the Adelaide plains were found to contain numerous maggots of the fly *Chortophila* (*Crinura*) *florigera* Zett. The fly was kindly identified by Mr. A. L. Tonnoir, who stated it was recorded by Malloch as *Hylemyia crinura*. The maggots were in the bulb portion of the onions, which were hollowed out and decaying. Attempts to get the fly to lay eggs on the plants failed. It may be that the presence of the maggots was secondary and not the original cause of the condition of the onion plants.

A local occurrence in mass numbers of the Rutherglen bug (*Nysius vinitor* Berg.) in a crop of linseed near Adelaide was recorded in January, 1931. In December the pest caused damage in certain areas in the South-East on turnips, carrots, parsnips, and potatoes. The Harlequin bug (*Dindymus versicolor* H.Sch.) occurred in plague numbers at Myponga in January and February, 1932, chiefly on potatoes and vegetables generally.

The red-legged mite (*Halotydaeus destructor* Tucker) occurred as a pest of seedlings in October and November, 1931, on nursery beds near Glenelg. It was recorded as causing damage to French beans, cucumbers, pumpkins, and tomatoes in certain districts in the South-East in October, 1931. Specimens were not submitted, but it is probable that the species in this latter case was *Penthaleus bicolor* Froggatt.

4. Fruit Crops and Vines.

The losses in the apple crop due to codlin moth (*Cydia pomonella* Linn.) in different years are associated with the alternating years of light and heavy cropping and the fluctuations in the moth population. With a normal codlin moth population the percentage of affected fruit generally will be higher in a light cropping year. The crop in 1930-31 was a light one, and losses due to this pest were more in evidence in some districts. Pears were heavily attacked in February and March in certain mid-northern districts which Mr. J. Harris, the district instructor, attributes to the light apple crop. In 1931-32 the codlin moth infestation was much lower than usual, and a heat wave in January evidently further weakened the second brood, since a fair proportion of dead larvae were found in tree bandages. The observations carried out by Mr. R. Fowler at Blackwood Experimental Orchard and by Mr. J. Harris in mid-northern districts show the value of baits as a guide to the timing of spray applications (see *Journ. Agric.*, South Australia, 1931, vol. 35, p. 222). Experiments on the value of white oils in the spraying programme against codlin moth are discussed by Mr. R. Fowler (*Journ. Agric.*, South Australia, 1930, vol. 34, pp. 354-368, and 1931, vol. 35, pp. 306-314), and by Mr. J. Harris (*Journ. Agric.*, South Australia, 1931, vol. 34, p. 829).

The silver striped vine moth (*Hippotion celerio* Stephens) was noted in South-Eastern districts. Larvae of the light brown tortrix (*Cacaecia postvittana* (Walk.) occur occasionally in grape bunches. Occasionally the rind of the orange is marked by the caterpillar of this species (see Davidson, J., *Journ. Agric.*, South Australia, 1932, vol. 35, p. 1381).

The cherry and pear slug (*Caliroa limacina* Retz. = *cerasi* Linn.) was recorded for the first time as a pest in South-Eastern districts in November, 1930.

The cherry green beetle (*Diphucephala colaspidoides* Gyll.) occurred in large numbers in the Glencoe district in November, 1930. Plum foliage suffered chiefly, but other fruit trees also. The pest did not recur in 1931. The curculio beetle (*Otiorhynchus cribricollis* Gyll.) was prevalent in both years. It caused damage to young citrus in southern districts in February, 1932, and was particularly prevalent on the Adelaide plains.

The following species of weevils are referred to by A. M. Lea (*Journ. Agric.*, South Australia, 1927, vol. 30, pp. 582-598) as occurring from time to time as pests of fruit trees in South Australia. *Otiorhynchus sulcatus* Fabr. appears to be restricted to the Mount Lofty Ranges, where it occasionally attacks apple trees. *Polyphrades longipennis Pasc.* sometimes feeds on the tips of apple twigs.

The elephant beetle (*Orthorhinus cylindrirostris* Fabr.) attacks the orange, peach, and apricot. The larvae tunnel in the branches, and the roots of young trees may be affected.

The strawberry weevil (*Rhinaria perdix* Pasc.) feeds on the flowers, fruit, and crowns of strawberry plants, the affected leaves having small holes eaten through them; the larvae tunnel in the stems of the plant. A small species (*Neomerimnetes australasiae* Faust.) sometimes feeds on the buds and leaves of strawberry plants in the Mount Lofty Ranges.

The apple blossom thrips (*Thrips imaginis* Bagnall) occurred in plague numbers throughout the orchard and vine districts during the spring of 1931. Late flowering varieties of apples like Rome Beauty suffered severely, but early varieties like Cleopatra largely escaped damage as they blossomed before the period when the peak emergence of the thrips occurred. Berry fruits also suffered heavily. Vines were heavily infested in November and December, but there was no definite evidence that the setting of normal bunches of grapes was seriously affected. The present position regarding the thrips problem in Australia is discussed by J. W. Evans (Commonwealth Coun. Sci. Ind. Res., 1932, pamphlet No. 30). *Isoneurothrips australis* Bagnall and *Thrips tabaci* Lind. commonly occur during winter and early spring.

In the Light's Pass district the return migrants of the green peach aphis (*Myzus persicae* Sulzer) were more numerous than usual in May. Eggs were present in the axil of the buds on the peach trees the following month, and isolated hatched individuals were found during July. This pest occurs generally throughout the State, but usually the infestation on the trees is light. Occasionally the outbreak is severe as in the spring of 1928-29. Winter oil sprays will control the pest by destroying the overwintering eggs. There is evidently a combination of factors which bring about a heavy spring infestation on the trees in occasional years.

The woolly aphis parasite (*Aphelinus mali* Hald.), which was first introduced into the State in 1926 at Blackwood Orchard, is now well established in certain of the cooler areas of the State, but appears to have difficulty in becoming established in the warmer mid-northern districts.

The harlequin bug (*Dindymus versicolor* H. Sch.) occurred in plague numbers in certain districts in the South-East during September, 1930.

The Rutherglen bug (*Nysius vinitor* Berg.) is generally present over a wide area. It causes some damage to apricots, peaches, nectarines, and is frequently in numbers amongst vines. It appears to be more destructive when early, dry summers occur.

The pear leaf blister mite (*Eriophyes pyri* Pagenstecher) occurs on some varieties of pears. It was in evidence in certain areas in the southern district.

The relation of certain insects to surface blemishes of oranges in the season 1931-1932 is discussed by J. Davidson (*Journ. Agric.*, South Australia, vol. 35, pp. 1381-1387).

5. MISCELLANEOUS OBSERVATIONS.

By means of trapping records made throughout the year at the Waite Institute, the following species of flies have been found to be the prevalent blowflies in the district:—*Calliphora stygia* Fabr., *C. augur* Fabr., *Microcalliphora varipes* Macq., *Achaetandrus* (*Chrysomyia*) *rufifacies* Macq., and *Lucilia sericata* Meigen. *Calliphora fulvicoxa* Hardy and *C. rufipes* Macq. also occur in small numbers.

The total catch of flies in the traps in the pasture areas on the hill slopes was small compared with the numbers taken in traps situated near to the sheep yards, which indicates the value of placing traps near to situations where sheep congregate.

The moth *Monopis ethelella* Newman was found infesting the soiled portions of two stored fleeces.

The beetle *Aphodius hourtii* Hope occurred in flight in large numbers in certain districts in the South-East on the night of February 9th, 1932.

The mite *Tydeus foliorum* Koch. commonly occurs on oranges on the trees, but appears to be a scavenger and not harmful to the fruit.

The sugar ant (*Iridomyrmex rufoniger* Lowne (¹)) infested a species of *Lagunaria* in the Waite Arboretum in February in both years. The bark on the young twigs was removed in places and their growth affected.

The pine chermes (*Pineus pini* Linn.) occurs on *Pinus insignis* and appears to check the growth of shoots on young trees.

The mite *Pediculoides ventricosus* Newp. was isolated from a sample of hay received from a district in which workers handling hay and chaff complained of "hay itch." Only a few females were obtained.

The dried fruit mite (*Carpoglyphus lactis* Linn. = *passularum*) was found infesting stored prunes.

The chicken mite (*Dermanyssus gallinae* DeGeer) occurred in large numbers in a vacant room. The mites were emerging through the floor boards; the cause of the infestation was evidently due to the presence of pigeons nesting under the floor at one end of the room.

A SMALL SHEARING SHED.

The accompanying illustration shows two plans—one a general lay-out showing forcing yards, sweating pens, &c., in relation to the shearing shed; the other plan showing suggestions for the lay-out of the woolclassing portion of the shed.

Two main ideas have been kept in view in planning this shed; the first being the easy handling of the wool from the time it is taken off the sheep until it leaves the shed in bales; the other being simplicity in the form and construction of the buildings.

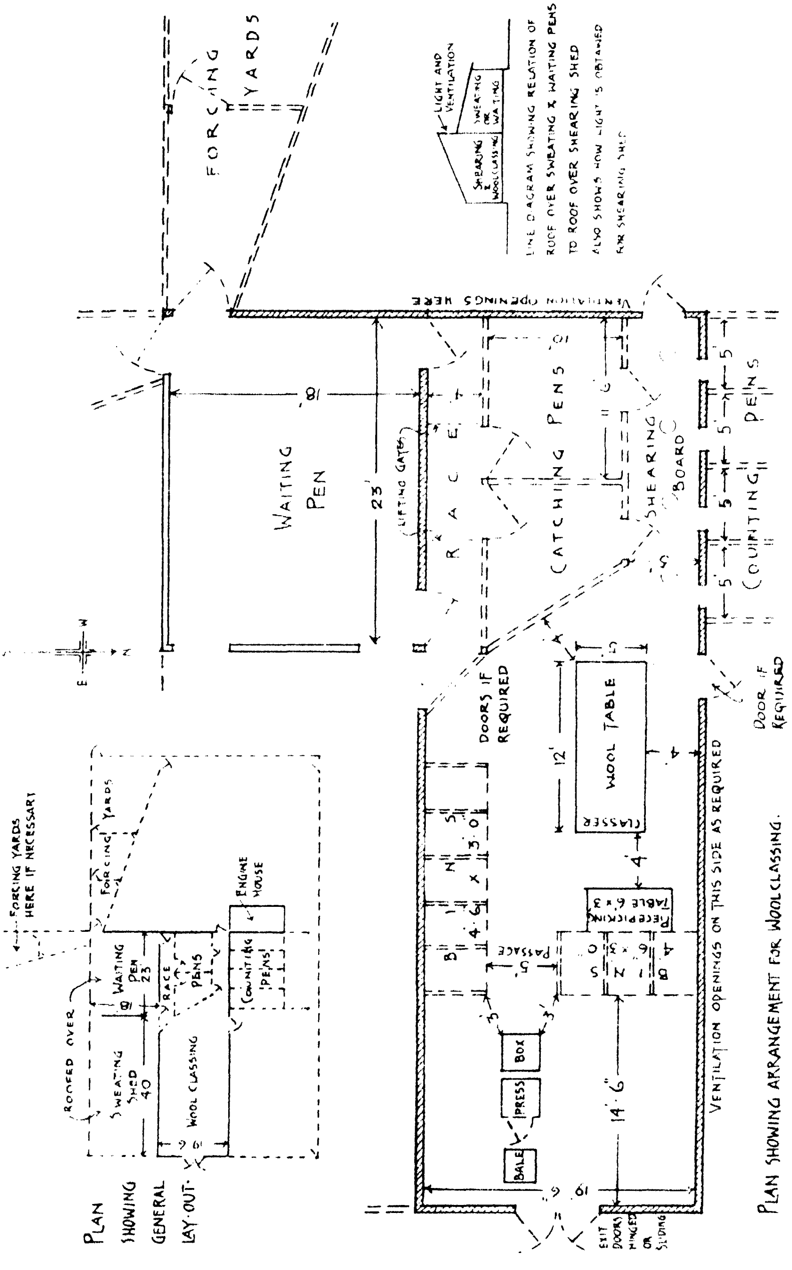
On the general lay-out plan it will be seen that the forcing yards can be placed either on the west or south side depending on local conditions. From the yards the sheep can be fed into the waiting pen or sweating pen, both of which would be covered with a lean-to roof as shown on the line diagram. The race can be supplied from the waiting pen of the sweating shed. From the race the sheep pass in to the pens to await the shearer. One pen to two shearers is shown.

The plan of the shearing shed shows positions for four sheares on the shearing board, with the counting pens alongside. Should the machine method of shearing be adopted the engine house can be placed as shown on the lay-out plan. Close to the shearing board is placed the wool table with the classer at one end. If desired, a separate table could be provided for the classer, and the wool table as shown reduced in size. Conveniently placed in relation to the wool table and wool press are the bins for the fleeces. A piece-picking table is shown in conjunction with a series of bins, which are also convenient to the wool press. Sufficient space is shown for operating the wool press and for the storage of bales if necessary. Exit doors for leading purposes are placed at the end of the shed. It will be seen that the wool is kept going in one direction from the time it leaves the shearing board until it passes from the shed in bales.

The area embracing the woolclassing, shearing board, pens, and race would be enclosed and covered with a roof of the saw-tooth type as shown in the small diagram. Light and ventilation would be obtained from the south side above the lean-to roof over the sweating shed.

(¹) Kindly determined by Mr. J. Clark.

The drawings have been prepared by Mr. T. A. Macadam, Lecturer in Building Construction at Roseworthy College, in conjunction with Mr. A. H. Codrington, Lecturer in Woolclassing, to illustrate the ideas suggested in this article.



AGRICULTURAL EXPERIMENTS IN SOUTH AUSTRALIA.

[By R. C. Scott, Supervisor of Experimental Work.]

(Continued from page 32.)

EXPERIMENTS IN THE MURRAY MALLEE.

The experimental plots in the Murray Mallee are situated at three centres, namely, Sandalwood, Copeville, and Yurgo. The agricultural conditions are a little different at each place, more particularly regarding the character of the subsoil, and therefore the results obtained are of special local interest. Experiments in progress consist of variety and manurial trials, whilst at Yurgo an additional series is included in which wheat is grown in rotation with lucerne seeded in the wheat stubble for grazing purposes.

During the course of the year inspection days have been arranged by the local Agricultural Bureaux, and visitors have had opportunity of noting the work being carried out. Keen interest has been shown both by the experimenters themselves and the Bureau members generally, and it is felt that results of value to the districts are being secured.

EXPERIMENTS AT SANDALWOOD.

CONDUCTED ON THE PROPERTY OF MR. K. A. BOWMAN.

The district of Sandalwood is approximately 120 miles east of Adelaide, and the plots themselves are about three miles north of the Sandalwood Railway Station. The nearest township of any size is Karoonda, which lies about 20 miles distant in a south westerly direction. The natural mallee timber is of medium size, and consists chiefly of *Eucalyptus oleosa* and *dumosa*.

The soil is of variable nature, but on the whole is of relatively light texture overlying a free-draining sub-soil, with some heavier flats and limestone outcrops. The experiments have now been in progress for five seasons, and as that was the term agreed upon, this constitutes the final report on the plots conducted by Mr. Bowman. During the five year period Mr. Bowman has been an interested and careful experimenter, and we take this opportunity of thanking him for his assistance.

Total	5·96	7·76	6·77	10·55	11·62	8·54

For the five years during which these plots have been in progress the rainfall has averaged 11.28in. per annum. The mean for the district taken over an eighteen-year period is approximately 14ins. per annum, and therefore the experimental crops have been produced under a fall of about 2¾ins. below the mean. The best years have been 1930 and 1931 with 12.32 and 13.27ins. respectively, whilst 1928 was fairly satisfactory as far as total rainfall is concerned with 12ins.

With regard to the Useful Rainfall, the average for 1927-31 is 8.54ins., but this is also considerably below the mean when the fall is calculated over a longer period. 1927 was a low rainfall year generally, whilst 1928 was characterised by heavy summer and light late winter and early spring rains. In each of the remaining years there was one critical month which caused appreciable depreciation in the crop returns, namely, August of 1929, September of 1930, and October of 1931. Therefore over the whole period the rainfall conditions cannot be regarded as altogether satisfactory for the carrying out of agricultural experiments.

1931	5 47	8 57	11 47	14 10	14 48	14 59
Means	5 10	8 33	10 48	12 3	13 16	13 41
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Value at 3s. 4d. per bush.	0 17 3	1 8 6	1 16 0	2 0 2	2 4 3	2 5 7
Net value with super. at 5s. per cwt.	0 17 3	1 6 0	1 11 0	1 12 8	1 14 3	1 10 7

Examination of the above results shows that with the exception of seasons 1927 and 1928 increased yelds have regularly followed heavier phosphate applications. In the two years mentioned the differences were not great, the averages for the five-year period indicating that the highest return has been harvested from the 3cwt. plot and the lowest from that receiving no manure, with regular improvement in yield for the intermediate dressings. The additional return following the application of the first ½cwt, of superphosphate has been 3bush. 23lb., with 2bush. 15lb. for the second, 1bush. 15lb. for the third, 1bush. 13lb. for the fourth, and 25lb. for the final 1cwt., constituting the 3cwt. dressing. The average returns therefore are 5bush. 10lb. for no manure, 8bush. 33lb. for ½cwt. of superphosphate, 10bush. 48lb. 1cwt. superphosphate, 12bush. 3lb. 1½cwt. superphosphate, 13bush. 16lb. 2cwt. superphosphate and 13bush. 41lb. for 3cwt of superphosphate. If these yields are reduced to a cash basis by allowing 3s. 4d. per bushel as the value of wheat and 5s. per cwt. as the cost of superphosphate, the highest nett return, namely £1 14s. 3d., has been secured from the area receiving 2cwts. of superphosphate per acre. Whilst the 3cwt. plot has given the maximum grain yield, the increase has not been sufficient to meet the cost of the additional fertiliser applied, and the net value of the crop so manured is approximately equal to that from the 1cwt. dressing.

The returns from the 1cwt. 1½cwt. and 2cwt. superphosphate applications do not vary to a great extent being £1 11s., £1 12s. 8d., and £1 14s. 3d., respectively. Therefore, the limit for profitable phosphatic manuring would appear to lie somewhere within the vicinity of 1½cwts. 45 grade superphosphate per acre.

Wheat Varieties, Sandalwood.

	1928.		1929.		1930.		1931.		Means. 1928-31.	
	B.	L.	B.	L.	B.	L.	B.	L.	B.	L.
Gallipoli	12	42	9	18	19	49	14	10	14	0
Nabawa	10	22	5	53	18	9	14	43	12	17
Currawa	12	49	5	22	15	50	14	6	12	2
Gluyas	10	21	5	45	15	59	11	12	10	49
Yandilla King	10	52	5	38	16	19	9	55	10	41
Caliph	9	55	6	10	13	30	12	26	10	30
Sultan	9	20	6	29	14	8	11	27	10	21
Ford	10	31	5	24	12	33	10	29	9	44
Daphne	10	38	5	20	12	55	9	42	9	39

As the varieties Nabawa and Caliph were not included in the 1927 experiments the yields for that year have not been included, and the means are calculated over the four-year period 1928-1931.

Gallipoli has headed the returns with 14bush. per acre, and is practically 1¾bush. ahead of any other variety. This wheat has yielded well throughout the mallee areas, almost invariably producing more grain than the appearance of the crop would lead one to expect, and appears able to respond under a great variety of soils and climatic conditions. The second position is occupied by Nabawa with an average of 12bush. 17lbs., followed by Currawa with 12bush. 2lbs. per acre, whilst the remainder have yielded considerably less.

From the above results it is evident that Gallipoli and Nabawa are the most valuable wheats for this district.

COPEVILLE EXPERIMENTAL PLOTS.

CONDUCTED ON THE PROPERTY OF MR. G. H. SUTHERLANDS.

Copeville is situated about 25 miles north of Karoonda and 20 miles north-west of Sandalwood. Whilst various classes of soil are to be found in the district, that which predominates carries a higher proportion of limestone than the general average of soils in the locality of Sandalwood. In addition the rainfall is somewhat less.

The experiments being conducted consist of wheat variety trials, manurial experiments relative to the optimum dressing of superphosphate, and rate of seeding tests; whilst this season small demonstration plots of various pastures have been seeded in order to ascertain their value under these conditions.

Rainfall at Copeville.

Useful Rainfall.

Seeding Rains (April-May)	1·09	1·09	2·85	1·68	1·72
Winter Rains (June-July)	1·70	1·80	2·48	1·99	2·35
Spring Rains (August-October)	2·44	5·07	3·95	3·82	3·95
Early Summer Rains (November)	0·94	0·32	0·83	0·70	0·73
Total	6·17	8·28	10·11	8·19	8·75

The average rainfall for the district is 11.44in., of which 8.75 falls during the growing period of the crop. For the past three years both the total and useful falls have averaged slightly below the mean with 10.70in. and 8.19in. respectively.

Whilst the total fall for 1930 was relatively light, the rains were well distributed, and despite a comparatively dry September the crops yielded better than was the case in 1931, when although more rain was recorded throughout the year the dry period experienced in October appreciably reduced the wheat yields. However in that year seeding rains were early and bountiful, with the result that self-sown crops were particularly good. Over the three years during which these experiments have been in progress the seasonal conditions have been relatively favorable.

Manurial Experiments, Copeville.

	No Super.	½cwt. 45 Grade Super. (11½lbs. P_2O_5).	1cwt. 45 Grade Super. (23lbs. P_2O_5).	1½cwts. 45 Grade Super. (34½lbs. P_2O_5).	2cwts. 45 Grade Super. (46lbs. P_2O_5).	3cwts. 45 Grade Super. (69lbs. P_2O_5).

1931	6 20	10 59	15 27	17 40	17 33	20 37
Means	7 5	11 59	15 4	15 45	16 4	17 51
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Value at 3s. 4d. per bushel	1 3 7	1 19 11	2 10 3	2 12 6	2 13 7	2 19 6
Net value with Super. at 5s. per cwt.	1 3 7	1 17 5	2 5 3	2 5 0	2 3 7	2 4 6

In each season the 3cwt. dressing has given the maximum grain yield, and over the three-year period has averaged 17bush. 51lbs. per acre. A very marked increase in yield has followed the first and second ½cwt. applications of superphosphate, and in this connection a dressing of 1cwt. 45 grade superphosphate has more than doubled the return of that from the no-manure plot, the actual figures being 7bush. 5lbs. and 15bush. 4lbs. per acre. Succeeding manurings have not had the same effect, and the increase between the 1cwt. and 2cwt. dressings is only 1bush, or 15bush. 4lbs. comparatively with 16bush. 4lbs. When these returns are reduced to net cash values by allowing 3s. 4d. per bushel for the wheat and 5s. per cwt. for the superphosphate, the most profitable crop is that harvested from the 1cwt. of superphosphate plot. This manuring has resulted in a net return of £2 5s. 3d. per acre or 3d. more than the 1½cwt. application. However, there is practically no difference in the value of the wheat crop secured from the phosphatic dressings ranging from 1cwt. to 3cwts. per acre, and therefore it can be concluded that superphosphate should be applied with the wheat crop at the rate of at least 1cwt. per acre, and preferably at heavier dressings if the residual effect on the grazing which follows is taken into consideration.

Wheat Varieties, Copeville.

	1929.		1930.		1931.		Means, 1929-31.	
	B.	L.	B.	L.	B.	L.	B.	L.
Canberra	10	27	21	3	22	45	18	5
Faun	8	59	23	16	21	25	17	53
Regent	9	54	23	17	18	15	17	9
Gluyas	10	40	21	51	17	40	16	44
Gallipoli	10	29	17	43	20	18	16	10
Felix	8	18	21	59	17	29	15	55
Gloss	9	13	20	39	16	59	15	37
Sultan	7	46	18	54	18	24	15	1
Sword	—		—		17	56	—	

In individual years Gluyas, Regent, and Canberra have headed the returns in the variety tests, whilst over the three-year period the latter has given the best average return with 18bush. 5lbs. per acre, closely followed by Faun with 17bush. 53lbs. per acre. Regent occupies third position with 17bush. 9lbs., whilst both Gluyas and Gallipoli have exceeded the 16bush. mark. Canberra is an early ripening Federation crossbred raised in New South Wales which has exhibited marked drought-resistant qualities. Faun was bred at Roseworthy College by mating Late Gluyas with Anvil, and has yielded well in certain parts of the Murray Mallee. Regent is also a Roseworthy crossbred, claiming Regal and Gluyas as parents, and resembles the latter in many respects. On the results obtained these three wheats can be recommended for this district.

RATE OF SEEDING EXPERIMENTS, COPEVILLE.

Experiments relating to the optimum rate of seeding for wheat sown on fallow ground were commenced in 1929. However, rabbits destroyed portion of the crop in 1931, and therefore we have only the results from two seasons to publish.

Seed per Acre.	1929.		1930.		Means.	
	B.	L.	B.	L.	B.	L.
30lbs.	7	14	18	52	13	3
45lbs.	7	46	18	54	13	20
60lbs.	7	43	17	35	12	39

Sultan wheat was seeded in each year together with 1½cwts. of superphosphate per acre. No conclusions can be drawn from two seasons' work, but it would appear that there is no advantage in utilising more than 45lbs. of wheat per acre on fallow ground in this district.

PASTURE EXPERIMENTS AT COPEVILLE.

This season a pasture variety trial was commenced in which seven varieties were seeded as pure stands in blocks each approximately one acre in area. The fodders planted consist of Wimmera Rye Grass, Perennial Rye Grass, *Phalaris tuberosa,* Lucerne, Clustered Clover, *Danthonia pilosa,* and Creeping Saltbush. These were seeded toward the middle of May on fallow ground, and manured with 1½cwts. of 45 grade superphosphate per acre. With the exception of the Clustered Clover and *Danthonia pilosa* a satisfactory germination resulted. Particularly strong growth has been made by Wimmera Rye Grass and *Phalaris tuberosa,* and it will be interesting to see whether the latter variety will be able to persist under these climatic conditions.

(To be continued.)

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR OCTOBER.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

This month, as the last, is one of the most critical periods in the control of pests, whether insect or fungus. To prevent the pests getting a start is the special endeavor of every orchardist; we know that the eradication is impossible; control is possible, though the weather has, of course, a lot to do with the effectiveness; but if we know what we have to control, and apply known good remedies at the proper time, we are doing all that we are able. The best of material applied too late is waste of time and money. For insect pests use arsenate of lead, and for fungus pests use lime-sulphur; a little atomic sulphur may be of advantage if added to the lime-sulphur when the weather is favorable to the spread of fungus diseases.

Use fine sulphur, with about 10 per cent. of air-slaked lime added, for dusting vines. This will control oidium; a bordeaux dust must be used (or the wet) if there is any sign of downy mildew.

For aphis use the black leaf 40, either wet or dry, as soon as the first insects are noticed; green aphis is about on peaches and cherries, and on some plums.

If mildew is noticed on strawberries, use sulphur with a little lime as above, but do not put on thickly; a light dressing is all that is required.

For codlin moth we still have to rely on arsenate of lead; the main thing is to have it on before all the petals have dropped; spray under as well as over, and then keep a coat all the time on the young fruit.

Borers may soon be seen on the foliage, and should be picked off.

Do not let young trees, especially citrus and vines, suffer from want of water, and keep the soil about them free from weeds.

Glass-house tomatoes will need close attention; remove sick plants and burn them; keep soil moist; open houses on very hot days, but closed at night.

Cincturing of Zante currants is done when the caps start to fall, but care is necessary in the operation. A very narrow cut is all that is required, and it should be through the bark, but no further.

Picking equipment should be in good order and clean.

STATE OF SOUTH AUSTRALIA.

ORCHARD, VINEYARD, AND MISCELLANEOUS CROP STATISTICS, 1931-32.

(Valuations of products are subject to revision.)

[By W. L. JOHNSTON, F.S.S., Government Statist.]

I. ORCHARDS.

Estimated Value of Total Products, £720,000 (£577,531).

1. *Acreage.*—29,077 (29,630) acres, decrease 553 acres; trees of bearing age, 25,835 (26,095) acres. Approximately 430 acres grubbed, mostly in Central Division, portion being replaced by vines. About 150 acres died out. Very little new planting.

2. *Production.*—Generally speaking, the chief crops were an improvement on the previous year, the most notable being—(*a*) *Apples*, 876,328bush. (486,773bush.), an increase of 389,555bush., but 475,936bush. below the record yield of 1,352,264bush. in 1927-28. (*b*) *Oranges*, 574,700bush. (409,816bush.), increase 164,884bush. established a record, the previous best being 411,508bush. in 1922-23. (*c*) *Pears*, 199,331bush. (127,883bush.), increase 71,448bush. The yield has been surpassed only twice, viz., 213,688bush. and 210,221bush. in 1927-28 and 1929-30 respectively. (*d*) *Other Fruits*—Details are shown in the accompanying table.

II. VINEYARDS.

Estimated Value of Total Products, £2,210,000 (£1,969,836).

1. *Acreage.*—52,498 (52,244) acres, increase 254 acres; vines of bearing age, 50,886 (49,521) acres. About 320 acres grubbed or died out, but more than counterbalanced by new plantings—about 580 acres—chiefly in counties Adelaide and Light, and to a lesser extent in counties Albert, Alfred, and Hamley.

The acreage was described as follows:—For winemaking 33,572 (33,053) acres, drying 18,379 (18,552) acres, and table 547 (629) acres.

2. *Total Grape Yield.*—118,401 (109,566) tons, increase 8,835 tons, average per acre of bearing age 2.32 (2.21) tons. For winemaking 59,202 (56,159) tons, drying 58,529 (52,516) tons, and table 670 (891) tons.

3. *Wine Made.*—10,680,000galls. (10,131,034galls.), increase 548,966galls., but well below the average of the previous five seasons, 13,269,269galls.

III. DRIED FRUITS.

Estimated Value (included in Orchard and Vineyard Sections), £810,000 (£669,721).

1. *Currants.*—156,393cwts. (151,761cwts.), increase 4,632. The quantity has been exceeded only twice, viz., 164,145cwts. in 1928-29 and 161,880cwts. in 1929-30.

2. *Raisins.*—Sultanas 159,591cwts. (111,599cwts.), increase 47,922cwts.—this is well above the previous five years' mean, 132,377cwts., but far short of the record, 188,503cwts. in 1929-30. Other raisins 25,096cwts. (44,903cwts.), decrease 19,807cwts.

3. *Other Dried Fruits.*—Apricots 12,881cwts. (14,956cwts.), decrease 2,075cwts., formed the main item. Other details are shown in table herewith.

IV. MISCELLANEOUS.

Estimated Value of Products, £410,000 (£325,659).

Market Gardens, 1,726 (1,663) acres. *Pumpkins and Melons*, 338 (379) acres, 1,941 (2,128) tons. *Tomatoes*, 603 (640) acres, 180,412bush. (169,825bush.); crop only once exceeded, viz., 232,622bush. in 1923-24. *Potatoes*, 5,996 (4,998) acres, 24,062 (18,991) tons; heaviest yield since 1913-14. *Onions*, 405 (407) acres, 2,994 (3,181) tons. *Other Root Crops*, 602 (684) acres, 3,623 (4,008) tons. *Nurseries*, 150 (148) acres.

V. OVERSEA EXPORTS.

The value of the total oversea exports of the products of vineyards and orchards for the year 1931-32 was estimated at £1,558,888 (£1,056,557), increase £502,331, the principal items being dried fruits £575,180 (£619,570), wine £800,587 (£418,240), apples £162,455 (£13,911). Interstate exports are not available.

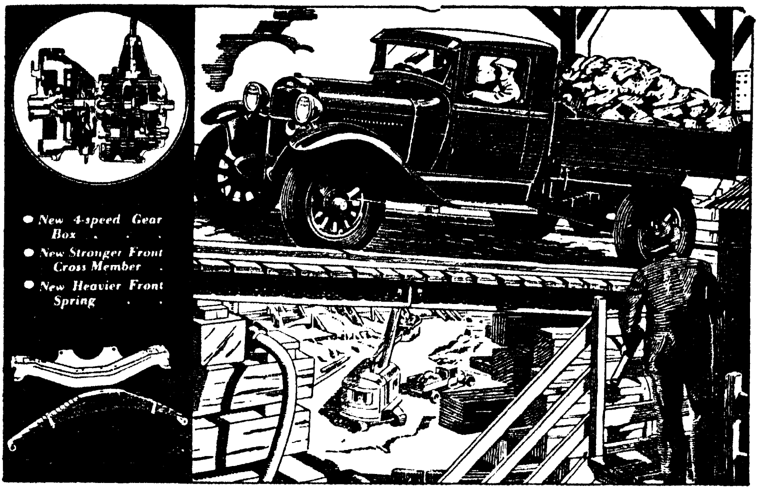
Manures.—In addition to 141,653 (182,906) tons manure used for crops as above, 7,054 (11,102) tons were used for top-dressing—the acreage top-dressed being County Adelaide, 22,409 (35,338); Hindmarsh, 22,984 (38,223); Light, 954 (4,711); Sturt, 9,504 (10,892); Buckingham, 4,340 (1,721); Grey, 26,476 (39,932); MacDonnell, 13,114 (17,550); Robe, 27,391 (31,446); others, 12,156 (24,726); Total 139,328 (214,539).



Greater strength and increased power . . . from these Ford Truck improvements!

THE recent important improvements to the Ford 30 cwt. Truck greatly extend the strength, performance and value of a truck already famous for its power, speed, strength, low price and low running costs.

Power and Speed **. . . . Tremendous pulling power and higher road speeds result from the New 4-speed Gear Box . . . 5 ball and roller bearings in the gear box mean that in all forward speeds the entire drive (from engine to road wheels) is on frictionless bearings . . . A Power Take-off is provided for tipping or for belt-work jobs.**

Added Strength **. . . . comes from the New Heavier 2¼" Front Spring and the New Stronger Front Cross Member. This re-designed, stronger front suspension will stand up to heaviest work at speed over rough tracks, and relieves radiator, engine, clutch and transmission from all road strains.**

Add to the above improvements the existing Ford advantages of torque-tube drive and radius-rod construction, and you have a 30 cwt. truck unequalled for Australia's strenuous conditions. The Ford is now a *heavy-duty* truck in every detail. Ford design relieves the springs of all driving strain, keeps axles always in alignment, reduces tyre wear and allows positive setting of brakes. Ford economy, too, is remarkable—3d. per ton-mile on a 100-mile-day basis is an average figure.

STATISTICS OF THE DAIRYING INDUSTRY.

1. Strength of Herds.—After a fall from 127,292 dairy cattle in January, 1927, to 104,255 in 1930, January, 1932, records a recovery to 127,756—464 greater than January, 1927—with a potential further increase from the 14,896 other heifers over one year old.

Year (Jan. 1).	Total.	In Milk.	Dry.	Heifers, Springing.	Other Heifers, 1yr. & over.
1927	127,292	86,172	32,289	8,831	12,719
1930...............	104,255	75,574	21,219	7,462	11,726
1931	109,672	79,805	20,406	9,461	13,591
1932	127,756	90,767	23,171	13,818	14,896

The Dairy Cattle were distributed as follows:—*Central Division*, 62,995 (County Adelaide 22,701, Hindmarsh 9,905, Light 7,920, Sturt 8,443); *Lower North*, 17,526 (County Stanley 5,834, Victoria 5,460); *Upper North*, 8,175 (County Dalhousie 3,065, Frome 3,338); *South-Eastern*, 17,230 (County Grey 13,007); *Western*, 6,976; *Murray Mallee*, 14,854 (County Russell 5,397).

2. Classification of Dairy Herds.—For the year 1932 there were 19,759 farmers recording dairy herds; 1931, 19,315; 1930, 18,866. The cows have been classified in the following groups:—

Year (Jan. 1).	Number of Herds in each Group.						
	1-4.	5-9.	10-14.	15-19.	20-29.	30-49.	50 & over.
1930	12,138	4,596	1,079	434	392	193	34
1931	12,026	4,939	1,230	439	451	203	27
1932	10,640	5,911	1,763	614	531	257	43
Divisions—							
Central	4,121	2,720	884	327	293	155	30
L. North	1,848	1,095	232	46	30	7	1
U. North............	742	458	124	31	24	11	—
S. Eastern	734	614	329	159	105	33	5
Western	1,522	359	40	10	2	1	1
M. Mallee	1,673	665	154	41	77	50	6

Comparing the last two years, the number of herds in the group 1 to 4 decreased to 10,640 (12,026), whereas all the other groups with large herds increased.

3. Production.—*Butter*—After six low years ranging from 10 to 13 million lbs. the production of butter for the year 1931-32 increased to 17,559,166lbs., exceeding the previous record of 17,244,389lbs. in 1924 by 314,777lbs. *Cheese* production also increased from the record of 1930-31 (3,901,159lbs.) to 5,109,933lbs. *Pigs slaughtered* 114,313 compared with 111,307 in 1930-31.

	1929-30.	1930-31.	1931-32.
Butter (lbs.)	10,789,706	12,961,213	17,559,166
Cheese (lbs.)	3,536,934	3,901,159	5,109,933
Pigs slaughtered (No.) .	94,950	111,307	114,313

4. Oversea Exports.—Record quantities of Butter and Cheese were exported to overseas countries:—*Butter*, 7,400,628lbs. (£370,560) compared with 2,456,894lbs. (£119,604) in 1930-31, and 659,061lbs. (£50,922) in 1929-30, *Cheese*, 898,847lbs. (£29,686). No cheese had been exported during the previous five years.

5. Factories.—The development of the dairying industries is reflected in the factories for Butter, Cheese, Bacon, and Ham. For the latest year of complete record (1930-31) there were 47 factories employing 739 hands with a wage bill of £93,477, an output value of £1,103,319, and with capital invested in factory land, buildings, plant and machinery to the value of £355,715.

RETURN OF EGGS AND EGG PULP EXPORTED FROM SOUTH AUSTRALIA TO EACH OF THE STATES AND TO OVERSEA COUNTRIES FOR YEAR ENDED JUNE 30th, 1932.

(Compiled by the Government Statist from returns specially collected from Exporting Merchants.)

SUMMARY OF PLANT DISEASE RECORDS IN SOUTH AUSTRALIA FOR THE TWO YEARS ENDING JUNE 30TH, 1932.

[By GEOFFREY SAMUEL, M.Sc., Waite Agricultural Research Institute, University of Adelaide.]

Rainfall.—The rainfall, which is the main factor influencing the development of plant diseases, may be briefly indicated for the years under review as follows:—

1930. A very late break to the season, with rainfall for the first six months much below the average; from July to October rainfall considerably above the average, so that the year closed with a total of 18.6in. at Adelaide (average 21.1in.).

1931. An earlier break and a cloudy, wet winter, followed by a dry spring. Total rainfall 22.3in. at Adelaide (average 21.1in.).

1932. An early break to the season, with rainfall considerably above the average for the first six months (14.54in., average 10.00in.), due mainly to an excess in April.

Cereals.—There was again comparatively little loss from take-all either year, except that in the Murray Mallee district in 1930 there was an appreciable amount of "whiteheads." This was probably due to late root infection with *Ophiobolus graminis* and *Helminthosporium sativum*, though in many cases not sufficient to cause blackening of the stem-bases. Red Rust or Stem Rust (*Puccinia graminis*) was moderate to severe in some areas in 1930—completely destroying some crops in the Loxton district—and light to moderate in 1931. Flag Smut (*Urocystis tritici*) was slightly more in evidence in infected districts in both years. *Rhizoctonia solani* and Nematodes or Eel-worms (*Heterodera schachtii*) occur in small patches in wheat and oat crops every year, mainly in the mallee areas. Cereal smuts were light in both years.

Pastures.—The Red Grass-destroying fungus *Isaria graminiperda* was reported from a number of localities both in the north and in the south-east in 1931. It attacked mainly *Poa bulbosa* in patches of limited extent. This is the first record of the fungus for this State. The introduced grass *Brachypodium distachyum*, which is spreading in the neighborhood of Adelaide, is very severely affected with smut (*Ustilago bromivora?*) almost every year.

Vines.—Further cases of what is considered to be salt injury to vines following the run of dry seasons were recorded. Frost in October, 1931, caused serious damage to vines in the Clare and Coonawarra districts. A case of court-noué was recorded from Waikerie in 1931, and a case of variegation of the leaves from Clare. With the early break of the season in 1932 considerable trouble was caused by the mould *Botrytis cinerea* in the currant drying areas. A little Anthracnose (*Gloeosporium ampelophagum*) was noted in 1930-31, but on the whole vines have been very free from disease.

Citrus.—The wet winter of 1931 was responsible for Brown Rot (*Phytophthora hibernalis*) causing considerable losses of citrus fruit in the non-irrigated areas, particularly the Inman Valley. Bacterial Spot (*Bacterium citriputeale*) was also more prevalent than usual. A stem-end rot of the fruit caused by a species of *Phomopsis* agreeing closely with *Phomopsis californica* was recorded in one case from Coromandel Valley. In another case a *Pleospora*, agreeing closely with *Pleospora herbarum*, caused a definite slow rot of a black leathery nature with reddish discoloration at the margins. Both these are new records for the State. A case of *Armillaria mellea* appeared on oranges at Kingston following the digging in of chips from the wood-heap. A few cases of Crinkle (cracking of the pithy part of the rind beneath the surface) were recorded from the drier areas.

Stone and Pome Fruits.—Silver leaf (*Stereum purpureum*) is gradually increasing in amount in the Adelaide hills, having been recorded on plums, apricots, and apples, and was also noted on Kangaroo Island. Black Spot or Scab of Apple (*Venturia inaequalis*) was more prevalent in 1931-32 than for some years past, but was not serious. Apple bark rot (*Physalospora cydoniae*) was reported from several localities. Curl-leaf of peaches (*Taphrina deformans*) was bad in the wetter districts in 1931, and Shot-hole or Scab of apricots (*Clasterosporium carpophilum*) was also more prevalent than usual.

Vegetables.—Irish Blight of potatoes (*Phytophthora infestans*) was more prevalent in 1931 than for a number of years, and was severe again in the early part of 1932, many tons of potatoes being lost in the Mount Gambier district. Bacterial Blight of French beans, agreeing in symptoms with *Phytomonas medicaginis*, var. *phaseolicola*, was also the cause of considerable loss of beans in both seasons. Celery blight (*Septoria apii*) was severe again, but control by spraying with Bordeaux Mixture is being more widely adopted. *Armillaria mellea* severely damaged one bed of parsnips and carrots at Kingston. Neck Rot of onions in storage (*Botrytis allii*) and Onion Smudge (*Colletotrichum circinans*) were both recorded for the first time, as also was a *Fusarium* wilt of watermelons.

Tomatoes.—Spotted wilt (virus) was generally distributed in both years, being more severe in 1930-31 than in 1931-32. A severe case of non-setting of the fruit due to Mosaic was recorded for a glasshouse. *Macrosporium solani* is becoming more prevalent in glasshouses, and *Fusarium lycopersici* was noted in a few houses. The mite *Phyllocoptes lycopersici* was noted on many occasions, both in glasshouses and outdoors, as also was the root-knot nematode (*Heterodera radicicola*).

Tobacco.—Downy Mildew or Blue Mould of tobacco (*Peronospora hyoscyami*) was more prevalent in tobacco seedbeds in 1931, and in the autumn of 1932 was found on some field crops. Tomato spotted wilt (virus) usually occurs only on odd plants, but in a small field at Mount Gambier in 1932 more than 30 per cent. of the plants were lost from this disease.

Ornamental Plants.—Irish blight (*Phytophthora infestans*) was recorded for the first time on seedling petunias in frames in 1931. *Rhizoctonia solani* caused a collar rot of sweet peas in a glasshouse at Marion, which was checked by the application of Cheshunt Mixture. Carnation rust (*Uromyces caryophyllinus*) was recorded for the first time. Hollyhock rust (*Puccinia malvacearum*), marigold rust (*Puccinia calendulae*), and sunflower rust (*Puccinia helianthi*) all occurred more than usual.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

A FEW IMPRESSIONS OF FUTURE TRADE PROSPECTS IN THE EAST FOR OUR FRUIT AND VEGETABLES.

[By Max J. Vickers, Lenswood and Forest Range.]

(*Paper read at the 43rd Annual Congress of the Agricultural Bureau, September,* 1932.)

I have been asked to give my impressions of trade prospects in the East, gained by two recent visits—one 12 months ago visiting the Philippines, China, and Japan, and the other to Java and Malaya, from which I returned one month ago. I will deal with the latter countries first.

Volume.

It is pleasing to be able to tell you our trade is increasing in most lines of produce, both in quantity exported from here and in percentage of imports into these countries. The stage was set for a great expansion but for the depression, which I am firmly convinced is even greater in Java and Malaya than in this country. Their main export crops—sugar, rubber, tin, &c.—are as a drug on the markets of the world. Java being one of the very few countries still on the gold standard, is finding it extremely difficult to sell anything. The Australian £ was worth only 10s. 10d. to 11s. 6d. there. This position, of course, would help us, as exporters, immensely, had not the people's purchasing power diminished to such an extent as to offset the value of the very favorable exchange rate.

I do not wish to give the impression that these countries are going to be able to absorb millions of bushels of apples, oranges, &c., like we are putting into the markets of the United Kingdom and Europe. The quantities taken as yet are relatively small, but this, I think, is going to increase yearly. There are 800,000,000 people living from India around to Japan. If only a small proportion eat some fruit we will feel the good effects of it. Witness the remarkable increase in wheat and flour exports to those countries because a small percentage of the population developed a taste for biscuits. It is becoming a greater problem each year to grow enough rice in some of these countries to feed their rapidly increasing numbers. America is exporting rice across the Pacific from California. The population of Java alone is now given at 41,000,000 on an area about twice as large as Tasmania.

Our exports of apples, oranges, &c., to this country comprise about 50 per cent. of its imports, America having most of the remaining trade, with a little coming from Japan and Manchuria. This must be considered fairly satisfactory, for it must not be assumed that it is within the power of Australia to capture the whole of such trade. The incidence of the respective producing seasons is a determining factor in this, and is something which must be borne in mind to get the possibilities of Australian trade with the Netherlands East Indies in the proper perspective.

Ports of Entry.

The chief ports of entry are Sourabaya and Batavia, although Semarang, Pekalongon, Tekal, and Cheribon are ports of call with the boat I travelled by practically no fruit is landed, this territory being chiefly supplied from Sourabaya.

Most importers work on both an indent and consignment basis, but prefer the latter if possible. Selling costs are very high. Importers seem to think they are entitled to about 100 per cent. on the landed cost.

Granny Smith is the most popular apple variety, followed possibly by Dunn's. With pears the varieties most favored are Packham's Winter Nelis and Josephines.

Expenses, as near as I could gather, are:—Per box—handling charges 15 cents, handing charge 15 cents, inspection 35 cents, duty 12 per cent. Currency is 100 cents to Guilder; Guilder 1s. 8d. in gold.

British Malaya.

Here we find the total value of imports of fresh fruits at about £300,000, about one-third of which is represented by fruits such as we could expect to compete for in the trade. This business is divided on about a 50-50 basis with U.S.A. In dried and preserved fruits, America has predominated, but with Australian figures during the last three years showing a steady increase. Of fruits in which Australia is interested, apples comprise nearly half of the imports, with grapes second on the list; these coming mainly from Western Australia.

Distributing Centre.

Singapore is the distributing centre for the whole of British Malaya and for the adjoining countries such as Siam and Burma. Considerable quantities are shipped or railed north in Malaya to Penang, Malacca, Ipoh, Kuala Lumpur, where large numbers of whites are engaged in tin dredging, &c.

Fruit Firms.

The Singapore Cold Storage Company (A. B. P. concern) is the largest, doing, I believe, more than half the business. This firm conducted me around for a day. They have admirable cold storage rooms, built specially for fruit, situated on the wharf. In the city they have another plant called the "Straits Ice Company," which is divided into a large number of small chambers holding, perhaps, 200 cases each, which are leased to dealers, enabling each one to have his stocks stored out of sight and knowledge of his competitors. (Temperature of 36 deg. maintained.)

I was given the opportunity to inspect apples from several Australian States, also American, and oranges, grape fruit, &c., from both countries. We checked

over a number of experimental shipments made by a Western Australian firm. These had arrived on the same boat as myself—the *M.V. Centaur*. Refrigerator cargo was in the better order, but deck cargo satisfactory, particularly where pre-cooling had been practised. In numbers of cases of oranges picked over, refrigerated cargo showed a loss of only 2 per cent.; deck cargo up to 10 per cent.

Some of the apples on the boat were given wretched conditions—were down on a lower deck with 1,500 live sheep herded around them. No canvas shutes were provided for ventilation. The heat and smell crossing the Equator was almost unbearable down there. I heard these arrived in bad condition, which was not to be wondered at. They would naturally lose their own delightful flavor and absorb that of the sheep.

MARKETS.

We spent considerable time going the rounds of the markets and visiting the Chinese merchants. One heard just an endless stream of complaints until in parting I told them I fervently hoped that some day God would send them a case of apples meeting their requirements. Whilst these people are inveterate "growsers," there is no doubt they are often let down badly. I was shown a line of several hundred cases of South Australian Cleopatras which these people claim were supplied for Granny Smith on an f.o.b. sale. These apples were yellow and badly marked by spray russet. Some being quite deformed by it; evidently having been grown by some primitive grower still using bluestone for black spot control. The fact of these apples not being cold stored prior to shipment and being allowed to become yellow, made them quite useless for this market, which must have them a green color. This represented a big loss to the importers.

A strict inspection should be made of all cases of apples marked "G.S." going over the wharf from here. This variety is being exported only in very small quantities from this State, yet I have seen whole loads branded "G.S." leaving for the ship's side. The biggest argument we have ever had with an apple buyer was through not allowing him to brand 200 cases of Stone Pippin as "G.S." in our shed. Consequently the apples left our shed nameless.

In the East I heard of several instances of this practice, which had thrown a spanner into the business cog wheel. Many people in this country need to get to know the Chinese business man better. They might get the rude shock of finding he is quicker on the uptake than they are.

I am pleased to be able to state that all dealers considered South Australian apples—received for the first time for a number of years—the best received from Australia with the exception of Western Australian "Granny Smith." They voiced their intention of getting their supplies from Adelaide next year—this generally before they knew to which State I belonged. However, they said they were finished with us for this year.

They consider we are an early State, as they had beautiful quality from us in March and April, but in July our apples were much too ripe. This gives a remarkable instance of the impressions gained by them by over-ripe fruit on their first season's acquaintance with us.

VEGETABLES.

I saw small stocks of vegetables carried over from the *Nieu Zeeland* shipment, which had been in cold store in Singapore for 25 days; these were still in good condition. They had peeled off the outer leaves of the cabbages, whilst all leaves had yellowed and fallen off the cauliflowers, allowing the heads to become somewhat dirty and discolored, but otherwise in good condition. They favor the heads being wrapped in cellaphane or some lunch wrap type of paper to prevent this—as practised by American exporters.

CELERY.

South Australian celery they claim to be too big, too green, and too coarse. As one dealer put it, "Plenty bamboo in Malaya—no want it from Australia." They ask for more of the outer leaves to be stripped off. I might mention that in that climate it is never cooked, but only eaten as a cold salad, or with cheese.

TRADE COMPETITION AND REFRIGERATOR SPACE.

There seems a very grave danger of the trade to the countries mentioned developing into a competitive one during the Australian season between the various States. If the exporting interests could confer, some form of space allotment or co-operation would be better than indiscriminate competition.

Refrigerator space on the *Centaur* and *Minderoo* from Fremantle up is very inadequate. The K.P.M. boats calling at Port Adelaide and going *via* the East Coast have considerably more. Both the *Nieu Zeeland* and *Nieu Holland* have 56,700 cubic feet divided into numerous compartments. The Burns Philp *Marella* has the small amount of 2,688 cubic feet. Refrigerator freight to Singapore is 110s. per ship's ton of 40 cubic feet. Refrigerator freight to Java is 100s. per ship's ton of 40 cubic feet. These are the main impressions gained during the trip to the Near East. I propose now to deal briefly with a trip to the Far East.

FAR EAST.

Places visited were the Philippines, Hong Kong, China, and Japan. Japan may be ruled out definitely; there is a 100 per cent. luxury tax imposed on fruit entering there. They grow very considerable amounts of apples and oranges and export them to many Eastern countries. Varieties grown are Newtown's, Romes, Winesap's, &c.

Whilst our percentage of trade to Near Eastern countries might be considered fairly satisfactory, there is surely room for a big increase in it to Hong Kong and China. At present—on 1930 statistics—we are shown as only getting from 2 per cent. at Shanghai to 8 per cent. at Hong Kong of the trade in various fruits and vegetables. I see no reason why this should not be increased to 50 per cent.

TRADE COMMISSIONERS.

The matter of Trade Commissioners being appointed for the East is receiving a good deal of prominence of late. To me this seems a necessity, although results will depend entirely on the right man being appointed. The British Government is finding it necessary to have more commercial representation up there. Until last year it had only three officers—one in Shanghai, one in Pekin, and one in Manchuria.

The average production of dairy cows in Great Britain is 574 gallons of milk a year; in Denmark, 571 gallons; Germany, 520; Norway, 445; Australia, 290 gallons.

THIS SHOWS THE URGENT NECESSITY FOR IMPROVING METHODS OF FEEDING IN AUSTRALIA WITHOUT DELAY.

USE

MEGGITTS
LINSEED
MEAL
FOR DAIRY COWS

Canada, with less than a quarter of the trade of the United Kingdom with China, maintains four officials, whilst the United States of America have 14. And the two latter countries seem to have the lion's share of the trading in such lines in which we can compete—wheat, flour, fruit, butter.

Most opposition to these appointments comes, I think, from those firms having definite trade connections with these countries. They have gathered experience and knowledge of trade requirements at the expense of much time and money, and do not agree that this should be made available to their possible competitors at no cost.

STORAGE.

Cold storage facilities are available at both Hong Kong and Shanghai for the carry over of fruit, at a cost of about 5d. per case per month. There is a powerful Fruit Merchants' Guild operating in Shanghai, and practically all imported fruit passes through the hands of this association.

RETAIL STORES.

We visited the largest department stores here to see their displays of fruit—the Wing On, and the Sincere Company—both founded by Chinese who made their money trading in Australia. These are larger than any department stores in Australia. These concerns, as in Japan and America, make a speciality of fruit selling in their basements, and work on finer margins of profit than can small shops selling fruit alone.

Oranges were on sale from Japan and America, and apples from Manchuria and the two first named countries, but none from Australia; celery, lettuce, spinach also from Oregon.

The purchasing power for these has to come mainly from 200,000 wealthy Chinese resident there. The foreign population numbers only about 53,000, of whom half are Japanese and several thousand of the rest consist of white Russian refugees who have not much buying power.

HONG KONG.

We are better situated to compete for the trade in Hong Kong and the Philippines than in Northern China. Empress (C.P.R.) boats make the trip from Vancouver to Shanghai, *via* Japan in 12 days, thus giving their exporters a great advantage over us for that market. Over 40 per cent. of the total oversea trade of China passes through Shanghai. Hong Kong has a fairly large European population; has an army garrison and a naval base; is also a great shipping centre.

PHILIPPINES.

We are the best situated geographically to get the trade of this country. It is the biggest market in the East—over 50 per cent. of all fruit and vegetables leaving California for the East goes to the Philippines. There are thousands of Americans drawing big salaries in gold dollars there, and their habits of eating fresh fruit and fresh vegetable salads in a big way have been taken up by the wealthy Chinese and the better class Filipinos. This group are reasonably close to Australia, whilst it is the last port of call for the C.P.R. and Dollar boats *via* Japan.

To meet American competition in these countries a big effort has to be made and sustained. To-day, through the exchange, we have a price advantage of which we should make full ues. Once we are well established on the market and our brands known, even if the price advantage is lost, we should have secured sufficient goodwill to maintain the trade on quality and efficient merchandising, against the forceful sales methods and adequate representation of American interests.

MAMMITIS, MILK FEVER, AND CONTAGIOUS ABORTION.

[By ALAN H. ROBIN, B.V.Sc., Government Veterinary Officer, Stock and Brands Department.]

(Paper read at the Forty-third Congress of the Agricultural Bureau, September, 1932.)

MAMMITIS.

Mammitis (or Mastitis) is an inflammation of the udder, and is one of the most formidable diseases of dairy cattle. The monetary loss annually sustained by the dairying industry in this State through the ravages of this disease must total to a very large sum indeed.

CAUSE.

All cases of Mammitis are caused by germs which have gained an entry into the interior of the udder, though the class of organism responsible may vary in different cases. The species of germ responsible for the majority of cases is known scientifically as a *Streptococcus*, but almost any of the numerous different kinds of filth germs which abound in dirt and dust and which have plenty of opportunities of getting on to the hair and skin of a cow's udder and hindquarters, through soilage of those parts, are able, under suitable conditions, to set up the disease.

There are two routes by which infection of the interior of the udder may take place, namely, (1) by way of the teat canal, and (2) through abrasions or sores on the skin of the udder and teats. Of the two, the former is the more common.

Invasion of the teat canal to some extent with germs is an event that is more or less continually taking place, as microscopical examination of the first squirt or two of milk from a quarter of any healthy cow will show. But, like any other animal, the cow is endowed with a certain degree of natural resistance to disease, and so long as she continues in good health and her udder is kept in sound order, these "invading" germs are got rid of out of the "bag" at milking time without having occasioned any harm. The udder is, however, a delicate organ, and, especially when in full milk, is very sensitive to any deleterious influences to which it may be subjected, and should any such be allowed to operate—as they often are in practice—then the germs are enabled to "go ahead" and set up the disease. Such injurious influences may be termed the "contributory causes of Mammitis," and the commonest are:—Severe chilling of the udder through exposure to cold and wet conditions, bruising and wounding of the udder by kicks, &c., rough milking (either by hand or running machines at too high a pressure), "over-stocking," and leaving the teats wet after milking, which causes them to become chapped and cracked.

MEANS OF SPREAD.

Mammitis is a contagious disease, readily transmissible from one animal to another. When caused by the *Streptococcus* germ it is especially contagious and will rapidly run through a herd if precautions are not taken. This form is carried from herd to herd and spread about the country through the movement of infected cows, and it is safe to say that the source of infection in an outbreak of this type of Mammitis in a herd is always the udder of a cow that is secreting the germs in the milk, even though the milk may appear to the naked eye to be perfectly normal in character.

The disease is carried from one animal to another, chiefly on the hands of the milkers and on the teat-cups of milking machines. The development of small hard nodules in the teat—commonly known as "pea in the teat"—is a frequent lesion of Streptococcal Mammitis, and cows with this condition are often difficult to milk. Recourse is often had to using a milking tube on them, and this instrument without any effective sterilization may be used on another cow, or on a different quarter of the same cow, and in this way the infection is spread. Infection may also result from the lodgment of germ-laden dust on the udder, especially at or about milking time.

SYMPTOMS.

These depend very largely on the virulence of the invading organism, and may range through every possible degree from very severe to mild. Usually at the outset a change is noticed in one or more quarters—they may become inflamed, hot, swollen, and painful. The milk secretion is diminished and soon changes in character; it may appear watery or blood tinged and contain small clots or curds. Later the clotted material increases and the whole secretion becomes thick and pus-like. "Stripping" becomes difficult, and through inability to remove the discharge, abscesses may form in the quarter and burst to the outside.

In very severe cases the udder may become highly inflamed and discolored, and little or nothing can be got away from the quarters. There is an accompanying disturbance in the animal's general health—she is "off feed," uneasy and feverish, and stands with back arched, hair on end, and is disinclined to move.

In mild cases, all that may be noticed is a transient slight swelling of the affected quarter accompanied by a slight watery or "stringy" appearance of the milk. These symptoms may disappear after a milking or two and give the impression that the animal has recovered. From time to time, however, they may recur, and the quarters gradually undergo a distinct thickening and become light in milk secretion.

Most dairymen are sufficiently conversant with the symptoms of Mammitis to be able to diagnose it readily when the attack is severe and the udder and the milk have undergone marked changes—then one can scarcely help recognising it. What is of much greater moment, however, is to detect the disease in its early stages, especially the very mild forms, so that the necessary control measures can be instituted before the disease spreads to other animals in the herd. With casual observation, these cases may often be overlooked altogether, or, if they are noticed, are thought to be of no great account. It should be recognised, however, that these mild cases are almost invariably cases of Streptococcal Mammitis which is the most highly contagious type of the disease, and they must therefore be treated just as seriously as the more acute forms. Any alteration in the milk should be viewed with suspicion, and if there is any doubt in the mind of any owner regarding a cow he can always submit a specimen of the milk to the Stock and Brands Department for examination.

TREATMENT.

Unfortunately, the curative treatment of Mammitis is still largely unsatisfactory and many failures occur under any known form of treatment. A great deal of benefit and many complete recoveries can, however, be effected by relatively simple methods of treatment if these are carefully carried out. They certainly involve much time and patience, but are nevertheless well worth while.

The first essential is to commence treatment early, and before the sub-acute and chronic stages have been reached; the longer the disease has been in existence the more remote the chances of recovery.

To begin with, the affected animal must be "strictly isolated" in suitable quarters and a dose of laxative medicine given such as 1lb. Epsom salts, ½lb. molasses, 2 tablespoonsful each of nitre and ground ginger, warm water 1 quart. In severe cases the dose of nitre can be repeated daily for three or four days. Diet should be light and laxative.

Local treatment of the udder comprises attention to the following matters:—

(*a*) *Hot Fomentations.*—These should be applied three times a day when the quarters are hot and swollen and should be continued until these symptoms subside. They are best done by applying flannel cloths wrung out in hot water, keeping the water hot throughout. Not less than half an hour should be spent at any one time doing this, and immediately afterwards the quarters should be rubbed over with some camphorated oil to prevent chilling and ease the pain.

(*b*) *Stripping.*—The affected quarters should be stripped out frequently. This is a vital part of treatment and should be done every two hours if possible; the nearer one can approach to doing it this often the better the chances of complete recovery. Stripping reduces the invading army of germs and removes the tissue damaging substances they produce, and by keeping the affected quarters as empty of milk as possible the germs are deprived to a large extent of their food supply, so that they cannot multiply so rapidly. By keeping their numbers down as far as possible in this way the animal's natural resistance to disease is afforded a much better chance of ultimately overcoming the trouble.

(*c*) *Massaging.*—After each stripping the quarters should be well massaged, firmly but gently, working from above downwards towards the teats and using some bland substance such as oil, lard, &c., as a lubricant for the hands and to prevent chafing. After each massaging, again strip out whatever milk has been brought down by this means into the milk cistern.

Stripping and massaging should be persisted in until the milk has returned to normal character.

All diseased milk from the affected quarters should be caught in an old tin or bucket containing disinfectant.

Milk tubes should not be used to empty the quarters, so long as it is possible by patient endeavor to strip them out by hand, but if used they must be thoroughly sterilized by boiling immediately before and after use. If abscesses form they should be opened when ready and bathed and syringed with weak Lysol (1 teaspoonful to 1 pint of water) or some other antiseptic. Should any hardening of the quarters persist, iodine ointment may be rubbed well in once a day.

For some time past considerable attention has been given to the matter of trying to cure Mammitis by means of vaccines, but results have proved very disappointing, and this method of treatment is to date of little value.

PREVENTION AND CONTROL.

Since curative measures are so often of little avail, the prevention of Mammitis is the all important matter to which dairymen should give the closest attention. Vaccine treatment in this connection has again so far proved of doubtful value, and the practice of proper dairy hygiene is still the great essential in controlling the occurrence and spread of this disease.

The matters that have to be constantly aimed at are, (1) the minimising, as far as possible, of the chances of germ invasion of the udder taking place, (2) the protection of the cows from exposure to the "contributory causes of Mammitis," namely, chills, "over-stocking," bruising of the udder, &c.

With these objectives in view, the sanitation and cleanliness of the cowyards and bails and of all utensils must be given strict and unremitting attention. Floors should be kept clean and free from litter, and if they can be regularly flushed down with water so much the better. Walls and partitions of the sheds should be thoroughly scraped down twice a year and fresh hot limewash applied. Milkers should always work with clean hands, and if machines are used, they must be thoroughly and regularly cleaned.

Prior to milking, the udders and teats of the cows should be thoroughly washed with soap and water and then dried with a clean cloth. The water used for these washings should be changed frequently and not kept in use until it becomes a solution of mud and filth. Several cloths should be kept for use and they should be boiled daily.

Where machines are used, before the cups are applied to the teats, all quarters should first be tested by milking a little from each and examining the milk carefully. After removal from a cow and before placing them on to the next one, the cups should be rinsed out with clean water, and should an affected cow be discovered after machines have been used on her, they should be cleaned with hot soda solution before using them on another cow. Care must always be taken to run the machines at proper pressure.

After the cows are milked and before turning them out of the bails, the udders and teats should be washed again in a little disinfectant solution and then dried carefully. This washing after milking is a very important matter, and yet is one that is very infrequently carried out. It clears off any germs and dirt that may have got on to the teats during milking, and it also removes the film of milk that usually gets on to the outside of the teats during milking and which if left there to dry in the wind after the cows are turned out is a prolific cause of cracked and sore teats. It has been definitely proved that there is an intimate relationship between sore teats and the occurrence of Mammitis, and their prevention is a matter to which dairymen must give more attention if the incidence of Mammitis cases is to be kept at a minimum. The washing of the udders and teats with disinfectant solution after milking also serves the useful purpose of disinfecting the milker's hands and so lessening the chances of virulent germs being thereby carried to the next cows they go to milk.

As far as possible, dry milking should be practised in preference to wet milking, and if necessary, the use of a little oil or vaseline as a lubricant is much preferable to the so often practised business of wetting the hands and teats with milk or saliva.

The greatest possible care should be exercised to sustain the vitality of the cows and their udders. One cannot always help weather conditions, and temporary ill health is always liable to happen, but the provision of good shelter and good feed should always be possible, and gentle handling practised. Cows close up to calving should not be allowed to get "over-stocked," and if necessary a little milk should be taken from the udders from time to time. The "drying off" of cows should be done carefully and thoroughly, and the animals should not be turned out and left to dry themselves off so long as they are secreting any appreciable quantity of milk. Improper and careless "drying off" of cows is undoubtedly responsible for many cases of Mammitis occurring when the animals come in again.

Immediately a case of Mammitis is discovered, the animal should, if possible, be strictly isolated until she has recovered. If complete isolation is not possible then she should at least be kept out of the milking shed until all the others in the herd have been milked first, when she can be brought in for treatment. If she is a poor producer she would best be dried off and sold to the butcher; little or no monetary loss will be incurred and it may prevent the spread of the infection to other animals in the herd. One should never handle a Mammitis case just prior to milking healthy animals, and care should always be taken to make sure that an animal that has been affected with Mammitis is thoroughly right again before returning her to the herd.

Finally, in order to prevent the possible introduction of this disease from outside sources, care should always be taken to isolate newly purchased animals for a few days, or at least to milk them last of all until it can be satisfactorily determined by careful manipulation of the udder and examination of the milk that they are free from the disease. It is by no means a sufficient proof that they are all right because on the day they arrive on the premises their milk appears all right. They may just happen to be in the incubating stages of the disease and in a few days' time it "shows up."

MILK FEVER.

"Milk fever" is a disease which affects milking cows usually within a few days of calving—occasionally it occurs shortly prior to that event.

The term "milk fever" is really an inappropriate one since, in fact, there is a complete absence of any fever at all, the animal's temperature being instead almost invariably subnormal at least during the most definite stages of the attack.

OCCURRENCE.

The disease is essentially one of heavy milkers, and it is therefore always one's best animals that suffer. Usually it does not attack a cow prior to her third calving (*i.e.*, when she is reaching the zenith of her production), though cases have been recorded among first and second calvers; and once an animal has had an attack she is liable to have another at her next calving. Many more cases of Milk Fever occur after an easy calving than after a difficult one, and well nourished animals, especially if they have been "dry" for several weeks, are more susceptible to attack than are cows in poor condition.

SYMPTOMS.

These generally develop within a day or two of calving, though they may be delayed for some weeks. Occasionally they may occur before the birth of the calf.

The first indications as a rule are those of unsteadiness, the cow appearing to have lost proper control of her movements. There is a general appearance of uneasiness denoted by continual shifting about or "paddling" of the hind feet, and when made to walk the animal moves with a stagger and may fall down. In some instances the preliminary symptoms are those of nervous excitement—the cow may bellow and rush about wildly, fall down and get up again, bump up against objects, and generally behave as if she has lost the sense of sight and direction.

These early symptoms are soon followed by increasing weakness, and the cow falls to the ground unable to rise, gradually becoming unconscious. In the majority of cases the attitude taken up is characteristic—the animal lying partly on its side, hind legs thrust out or drawn up under the belly, while the head is turned back against the side of the chest. If the head is straightened out and then let go it immediately falls back to its previous position.

Occasionally the animal lies stretched out flat on its side. Usually the eyes are half closed, dull in appearance, with the surface dry, but at times they are completely closed as if the animal is asleep. The animal may groan and grind the teeth, or the mouth may be partially opened, with saliva dribbling away. Paralysis of the throat is present, and the animal cannot swallow. There is also suppression of both bowel and bladder action.

Breathing may be heavy and "snoring" in type. The secretion of milk is diminished, the udder being loose and soft. The temperature may be as low as 95-98°.

As a rule, the general appearance of an animal suffering from Milk Fever is very characteristic, and this together with the history attaching to the attack makes correct diagnosis a comparatively easy matter to anyone who has had any previous acquaintance with the disease.

TREATMENT.

As the course of this disease is as a rule very rapid, treatment should be given as promptly as possible, but so long as there is still a spark of life left in the animal it is "not yet too late."

While there are other treatments available to the qualified veterinary surgeon, the only one that is suitable for the average stockowner is the wellknown one of inflation of the udder. This is an easy simple treatment, and one that has proved wonderfully successful when properly carried out. The procedure to adopt is as follows:—

First remove all milk from the quarters and then thoroughly wash the teats and udder with soap and warm water, or a weak solution of lysol. Then after drying place a clean cloth or towel under and in front of the udder to prevent it and one's instruments being soiled by contact with the ground. The teat catheter or milking tube of the pumping apparatus is then introduced into the teat canal and held in position with thumb and finger while the quarter is pumped up with air until it is uniformly tense. The teat tube is then withdrawn, and to prevent the escape of air the teat can be tied, not too tightly, with a piece of ½in. tape. This procedure is carried out with all four quarters in succession, the underneath quarters being inflated first. After all quarters have been so treated, they should then be gently massaged.

Special Milk Fever outfits are obtainable for inflation of the udder, but an ordinary bicycle pump attached to a valve from a bicycle tube can be used just as satisfactorily. It is essential, whatever the apparatus used, that it be thoroughly sterilised before use by boiling in water for five minutes, and after removal from each teat and before insertion into the next, the milk tube or valve should be rinsed out in a weak solution of lysol. The operator must also take due precaution to clean up his arms and hands thoroughly before starting his work. These antiseptic precautions are all very necessary in order to prevent the introduction of dirt and infection into the quarters which would give rise to an attack of Mammitis.

After the udder has been pumped up, the cow must then be propped up on her chest and a bag of wheat, super, or some other substitute placed behind her shoulder to help keep her in that position. *On no account should she be allowed to remain lying stretched out flat on her side,* otherwise a fatal pneumonia is likely to supervene. She should also be covered over with a good rug or two or several empty bags to get her warm and stimulate body circulation.

On no account should any attempt be made to drench a cow that is down and unconscious with Milk Fever. The animal while in that state cannot swallow, and a drench will almost invariably enter the lungs and cause death by pneumonia. Leave any treatment of this kind until after the cow is upon her feet again.

After inflation of the udder has been performed the animal will as a rule recover in a comparatively short time. If she is not up on her feet within four hours the treatment should be repeated.

When the cow has got up on her feet again after the attack, the udder should not be milked right out for two or three days. If this should be done earlier, the animal is very likely to suffer a relapse and go down with a second attack from which it will be much more difficult to bring her round.

CAUSE OF THE DISEASE.

From time to time many different theories were advanced to account for this disease, but none of them was capable of standing up to scientific inquiry. More recently, Veterinary research workers, notably Professors Russell-Greig and Dryerre, of Great Britain, showed that the actual cause of an attack of Milk Fever was a deficiency of Calcium (or Lime) in the animal's blood stream, occasioned by the sudden transition of the udder from the dry to the lactating stage, with the consequent secretion of large quantities of Calcium in the milk—colostral milk being particularly rich in this mineral element. They showed, briefly, that when a cow was down with Milk Fever, the Calcium content of her blood was from 20 to 60 per cent. below normal; that inflation of the udder with air, by checking milk secretion brought about a rapid rise in blood calcium to normal again, the severity of the symptoms diminishing in proportion as the rise took place; and that recovery from an attack could be very rapidly brought about by the intravenous injection of specially prepared solutions of Calcium.

As a result of the discovery of the real cause of Milk Fever, treatment of cases by means of injections of Calcium solutions is now being practised to a considerable extent by veterinarians with marked success. In the hands of inexperienced persons, however, this method of treatment is extremely dangerous, and may cause death of the animal. For the present, therefore, until this treatment is simplified, "inflation of the udder" must still remain the "sheet anchor" of the stockowner.

PREVENTION.

Up to the present time, no methods have been evolved that will guarantee immunity from this disease, though the recent discoveries of the research workers ir connection with its cause and treatment indicate that if it cannot be wholly prevented there is at least quite a definite possibility of being able to lessen its incidence and the severity of an attack, and it is recommended that Calcium Chloride in 1oz. doses dissolved in 1 quart of cold water be given as a drench once or twice daily for two or three days prior to and after calving. This will provide the cow with a readily available supply of Calcium to help tide her over the "critical period" until her system can mobilise its body reserves of this element and utilise them to maintain the blood Calcium at its normal level.

It is further recommended that two or three days prior to calving, susceptible animals be given a dose of laxative medicine, and that during the first two or three day of milking they should not be milked completely dry.

In order to build up their body reserves of Calcium (and Phosphorus) which have become depleted by long-continued lactation, it is good sound practice to "dry off" one's in-calf cows, if possible, six to eight weeks prior to calving, and during this rest period supply them with a mineral supplement in addition to their ordinary feed. Suitable mixtures for this purpose are:—

1.	Di-Calcic Phosphate	1 part.
	Common Salt	2 parts.
2.	Sweet Ground Bone Meal or Superphosphate	1 part.
	Common Salt	1 part.

These may be used as licks, or be given mixed with the feed at the rate of 1½ozs. to 2ozs. per head daily.

Since Vitamin D is known to exert a very powerful influence in stimulating the absorption of Calcium and Phosphorus into an animal's system, it is desirable, if possible, to provide the animals with liberal amounts of greenfeed (which is rich in this vitamin) in their daily ration.

CONTAGIOUS ABORTION OF CATTLE.

Contagious Abortion of Cattle (or Abortion Disease as it is also commonly known) is a specific highly contagious disease characterised in the main by the act of abortion.

At the present time it is prevalent in practically every country in the world, causing tremendous economic loss to dairy farmers through the loss of aborted calves, diminished milk yield of aborting animals, and, in many animals, sterility. Its incidence in our dairy herds of South Australia is unfortunately high and tending to rapidly become still higher, and in their own interests owners should take more active steps to control its ravages than they have hitherto taken. There is still far too great a tendency in general on the part of dairy cattle owners to attribute their early cases of abortion to accidental causes, and to do little or nothing in the matter until it is too late. While Abortion may occur as the result of accident, rough handling of cows while heavy in calf, or as a sequal to other diseases, it should be realised that such cases are very few and far between. By far the vast majority of Abortions that occur in dairy cattle are caused by this specific infection, and the wisest policy for any owner to adopt is to treat every case as contagious until definite proof to the contrary can be obtained.

Cause of the Disease.

The disease is caused by a small germ known as *Brucella Abortus,* or the Bacillus of Bang. When this germ gains entry into the body of a pregnant animal it locates itself in the uterus (or "breeding bag"), where it rapidly multiplies and sets up a catarrhal inflammation of that organ, which results ultimately, as a general rule, in expulsion of the foetus (or calf). In the non-pregnant animal it locates itself in the udder, where it remains until the cow becomes pregnant, when it passes into the blood stream and is carried to the uterus.

The germ will live in these two organs, viz., the uterus and udder, only when they are functioning. In other words, it does not find them a suitable habitat in an animal that has never been bred. Hence there is little danger of heifers contracting the disease until after they have been put to the bull. As soon as they become pregnant, however, they become highly susceptible to infection. Viable calves born of infected cows do not become permanently infected, although at the time of birth they harbor innumerable germs in their digestive organs as the result of swallowing some of the foetal fluids. These germs rapidly disappear from their systems through being passed out in the faeces.

The foetus, afterbirth, and uterine discharges of an infected cow all literally teem with abortion germs, and these, in practice, constitute the highly dangerous media for the further spread of the disease. After the expulsion of the foetus the germs persist in the uterus for several weeks—on the average about two months—after which they leave that organ and locate themselves in the udder, where they remain until the animal again becomes pregnant.

Methods of Infection.

At one time it was commonly believed that infection took place *via* the route of the genital track, and the bull was held to be mainly responsible for spreading the disease through mechanically transferring infective material from the vagina of one cow to that of another by the act of "service." It is now known that although infection can take place by the vaginal route, it is not common, and the role of the bull as a spreader of the disease is a subsidiary one only.

By far the most frequent path of infection is by the mouth—through swallowing food and water which has been contaminated by the uterine discharges from infected cows, and in practice, grazing over contaminated pastures constitutes the chief means by which susceptible animals contract the disease. They may also become infected through licking the hindquarters of cows soiled by infective uterine discharge.

So far as the bull being the means of spreading the disease through "service" is concerned, the dangers are limited mainly to the following:—

(*a*) If allowed to serve infected cows with a discharge, he may passively transfer some of this to the hindquarters of other cows subsequently served from where it can be licked off by susceptible healthy animals.

(*b*) Occasionally a bull will become systemically infected, when he will harbor the germs in his genital organs and passages. Through his use for "service" a leakage of possibly infected semen from his penis or from the vaginas of cows he has served may contaminate the feed and drinking water of the herd or the hindquarters of the cows.

Experimentally it has been proved that infection can take place through the conjunctiva of the eye, and through wounds in the skin, but these are probably not common routes in practice.

COURSE OF THE DISEASE.

The usual result following infection is Abortion. Some cows, however, may become infected, and yet never at any time abort, and because they do not do so they are never suspected of being infected. Yet at each calving they can actively spread the disease and consequently act as "carriers."

After aborting once or perhaps twice, an infected cow will usually carry her subsequent calves to full term. This must not, however, be taken as an indication that she has thrown off the disease and is no longer a danger to other susceptible healthy animals. Once a cow has become infected with Abortion Disease she remains so for the rest of her life with very few exceptions, and although she becomes "tolerant" to its ill effects she is still just as active a spreader of it at each and all of her subsequent apparently normal calvings as she was when she first aborted.

SYMPTOMS.

An animal affected with this disease usually displays practically no symptoms until the act of abortion takes place, though, in come cases, she may give some premonitory signs of "springing." If abortion should occur early in the pregnancy it may pass unnoticed, and the first intimation of anything untoward is the "return" of the animal to the bull when she was thought to be safely in calf. This point should be remembered by owners, as early abortions are not uncommon, particularly in heifers. The "return" of the animals to the bull is usually not connected with Abortion disease but thought to be merely a "failure of the young stock to breed," and without any attempt to clear up the matter they are put to the bull again at the first opportunity.

When abortion takes place in the later stages of pregnancy the foetus is usually dead when expelled, and in the majority of cases the foetal membranes (or "afterbirth") are retained. There is a discharge from the uterus of a dirty yellowish-brown colored fluid which is often evil smelling and frequently persists for some weeks.

WHAT TO DO IF A COW ABORTS.

If an animal aborts in a herd that has hitherto been free of such events, she should be suspected of being infected with Contagious Abortion and immediately isolated. The aborted foetus and "afterbirth" should be destroyed by burning or burying in quick lime, and if the abortion occurred in the paddock the ground where it happened should be covered liberally with lime or some disinfectant. If it occurred in a stall to which other cattle have access this should be thoroughly disinfected and any litter or bedding burnt. The cow should be kept in strict isolation until the point is decided whether she is infected or not, the vaginal passage douched out daily with lukewarm ½ per cent. lysol solution or a weak Condy's solution, and all discharges and bedding disinfected before removing them from her quarters.

Take a sample of her blood and forward it to the Chief Inspector of Stock, Adelaide, for testing.

To collect the blood sample, clip hair at tip of tail and with a sharp knife make a cut ½in. to ¾in. long at the tip on the under surface. The blood can be caught in a bottle that has previously been sterilised and thoroughly dried. About an ounce (2 tablespoonfuls) should be collected, and after it has clotted in the bottle shake or strike the bottle sharply with the hand to loosen the clot from the sides so that it can contract and allow the serum to separate out. Then post sample on without delay. If the sample has to be sent from a great distance or the weather is hot it is preferable to leave the blood stand for some time and then decant the clear serum off into another clean dry bottle and send it only along—this is all that is used in making the test.

If possible the animal should be handled and treated by an attendant who does not handle the milking herd, and on no account should it be put to the bull before the result of the blood test is known. If this should be "positive," then control measures should be instituted with the herd.

CONTROL.

There is as yet, unfortunately, no known cure for Contagious Abortion, though many "nostrums" have been placed on the market from time to time for use in this direction. Vaccines of various kinds have also been tried without success. Once the disease has got into a herd all that can be done is therefore to apply suitable measures of control to prevent it from spreading to animals that it has not yet reached, and to work, where possible, towards ultimately eradicating it from the herd.

When the disease has made its appearance in a herd, the soundest step at the outset is to take samples of blood (in the manner previously described) from every animal of breeding age—male and female—in the herd and have them submitted to a special test known as the Agglutination test, by means of which infected animals can be singled out from non-infected ones with a great degree of accuracy and the point determined just how the herd stands with respect to infection. This knowledge is of great assistance in enabling an owner to decide what measures of control to adopt to deal with the disease.

The methods available for the control of Contagious Abortion fall into three main groups or schemes. In setting these out it is not possible on paper to deal with the varying factors which may affect their adoption on different farms—all one can do is to indicate the general principles in the hopes that individual owners can adapt them to suit their particular case. (An owner is always at liberty when in Adelaide to consult the Veterinary Staff of the Stock and Brands Department and discuss his problem in detail with them).

The schemes are respectively—(1) The Elimination Method. (2) The "Two Herd" Method. (3) The Isolation Method.

1. *The Elimination Method.*

Under this plan, all infected animals as they are detected by means of the blood test are immediately disposed of off the place.

After the disposal of the infected animals ("postive reactors") detected by the initial blood tests of the whole herd, the remaining cattle ("negative reactors") should be moved to fresh pasture away from any possible infected area, the pasture where the "reactors" were grazing being either cultivated or left unoccupied for six months to rid it of any possible infection before re-stocking again with susceptible animals. Fresh, clean milking premises should be established, or if this is not practicable the old premises thoroughly disinfected.

To detect any animals that may have been incubating the disease and which gave a negative or doubtful reaction to the first test, further blood samples are taken at intervals of four to six weeks, and this testing continued until on three successive occasions all animals give a negative reaction. The herd can then be considered to be free from the disease, and precautions should be taken to ensure that the disease is not re-introduced through any new purchases.

Any calves from infected cows can be handled as set out in Method No. 2.

This plan is applicable to herds where the blood test of all animals shows that the incidence of the disease in the herd is low, and although it may seem to some a drastic method, it is undoubtedly the most satisfactory one to employ in such herds, as by it it is possible to quickly eradicate the disease with a minimum of economic loss.

2. *The "Two Herd" System.*

Under this plan all infected animals are kept on a separate portion of the farm away from the non-infected ones so that the farmer has actually two herds—one infected and one free from Abortion.

When the result of the whole-herd blood test is known, the "positive reactors" are retained on that portion of the farm in use at the time and the remainder ("non-reactors") removed to a clean pasture. If possible, separate watering facilities should be provided for them, also separate milking premises and attendants who do not handle the infected cattle. If, however, all cattle have to be milked in the same shed the infected herd should always be milked last and the shed and all utensils subsequently cleaned and disinfected. Further samples of blood from the herd of "non-reactors" should be tested every four to six weeks, and any animal found reacting immediately transferred to the dirty or infected herd.

As calves born of infected mothers do not retain the infection, they can be kept and isolated until a few weeks after weaning, when, their blood having been tested and proved negative, they can be transferred to the clean herd.

The infected herd will, of course, be gradually disposed of as they outlive their usefulness, and the young stock grow to replace them, and ultimately an abortion free herd will be obtained. It is necessary, of course, after the last of them have been disposed of, to ensure that the pasture occupied by them is left for six months to get rid of infection before running the clean herd on to it.

If the infection is so widespread in a herd that there are but few clean animals in it, the whole herd could from the outset be considered simply as an infected herd and the disease allowed to run its natural course amongst the mature stock. A small clean portion of the farm should be left for the nucleus of a clean herd, which would consist of the heifers that have not reached breeding age and weaned calves that have given a negative blood test.

The future clean herd would then be gradually built up with the further calves of the infected mothers, and with the gradual weeding out of the infected mature stock the disease ultimately eliminated from the premises.

It would be necessary, of course, by simply anticipating requirements, to gradually increase the extent of clean pasture on the farm to accommodate the growing abortion-free herd.

This system is applicable to herds where the few infected cattle in them are too valuable to be summarily disposed of as in Method No. 1, or where the incidence of the disease is too high to allow of that plan being practicable. The owner must, of course, have the facilities for running the two herds so that they do not come in contact.

It must not be forgotten that the bull is an important factor in both of these two methods, and if possible only a known clean one should be used with the abortion-free females. His blood should be tested from time to time, and if found "positive" he should on no account be used any further on them. He should be kept confined to his own yard or paddock, and all "service" should be under control.

3. *The Isolation Method.*

This method of control can be used in herds in which the disease is fairly widespread and the general circumstances such that neither the elimination nor the "two herd" system is practicable. It has the serious objection that it only aims at keeping the ravages of the disease in check, while allowing it to remain in the herd. It is necessary to discuss it, however, since it is probably the only way the disease can be handled in many infected herds in the State.

The plan is based on the facts set out earlier regarding the means by which the disease is spread from one animal to another, and consists of so handling the herd that escaping Abortion germs from infected animals will have the least opportunity of being picked up by susceptible healthy ones.

In handling Abortion by this method it is necessary to set apart portion of the premises to be used solely for "calving" purposes, and these quarters should be so placed that infective material cannot drain from them and contaminate the feed and drinking water of the herd. Every breeding animal in the herd must be treated as a possibly infected animal and be removed to these quarters before she is due to calve, or immediately she shows any signs of impending abortion. For the purpose of detecting any "aborters" in good time so that they can be got away before they have a chance to infect the pastures through their uterine discharges, it will be necessary to keep a close regular watch over all "in-calf" animals, especially heifers.

Every animal, whether she calves normally or aborts, should be douched regularly and kept segregated for at least four to five weeks after all discharges have apparently ceased. All by-products of abortions and normal calvings and bedding should be effectively disposed of and the premises finally disinfected after each time they are used. Care should be taken to avoid carrying infective material on the hands and clothing after attending to the animal.

The bull should be kept in his own yard and not allowed to run with the herd. He should not be allowed to serve any cow within two months of her aborting, or any cow with a discharge. His sheath should be douched with antiseptic solution after each "service."

Calves should be kept in their own special yards and not allowed to run with the cows for some weeks after they have been weaned.

The milking premises of the herd should be kept clean, and if any milk is spilt on the floor the place where it happened should be covered with lime or other disinfectant.

While aborting animals that are not really profitable may be fattened and disposed of—those that are of especial merit need not be immediately got rid of under this plan. In fact they are better retained unless they prove sterile, for most of them will probably never abort again, and they can be handled without much danger of their spreading infection. By keeping them as long as they are profitable, the necessity of bringing in fresh possibly susceptible animals from outside to keep up the strength of the herd is avoided as much as possible, and in this way the disease is not kept so "active" and its ravages are reduced to a minimum.

PREVENTION.

Where a herd is clean the fullest precautions are necessary to prevent possible entry of the infection. The greatest danger by far is that the disease will come in through the medium of additions to the herd. The fundamental procedure of prevention in this connection is to raise sufficient heifers to replace adult animals. If outside purchases have to be made, buy only from known clean herds, or buy animals between weaning and breeding ages. If adult animals have to be purchased (which is usually necessary at some time or other), they should be strictly isolated until two blood tests at four to six weeks' intervals prove to be negative. It is not sufficient to isolate new females until they have calved as normal calving is no proof that they are "clean."

The bull in a clean herd should be limited to use with the cows of the herd if possible and not used for service with outside cows.

If untreated milk and other factory by-products are brought on to the farm for feeding to calves and pigs precautions should be taken against the possible introduction of infection in them. They should be sterilised by boiling and also the "containers" used for collecting them from the factory.

THE PATERSON SCHEME.

[By A. J. Cooke (Vice-Chairman, Advisory Board of Agriculture).]

(Paper read at the 43rd Annual Congress of the Agricultural Bureau.)

The Paterson Scheme has been in operation now for a number of years, and although much publicity has been given to the great benefit that it has been to the dairying industry in Australia, there are still some dairy farmers, commercial men, and others who, through the press and on the public platform, criticise the operations of the Scheme, and appear to think that it is a burden rather than a benefit to dairymen of this State.

Briefly let us examine the position. Is the Paterson Scheme justified? What is it? How does it operate? It is first necessary to draw attention to the conditions of the dairying industry some years ago before the marketing scheme was put into operation. At that time dairymen had to accept, for a large and constantly increasing portion of each year, export parity rates, not only for butter they sent overseas, but also for what they sold in Australia. That rate invariably ruled the local price when there was an exportable surplus.

When butter supplies were short it was possible to get a little more for the butter on the local market, but about the time this scheme was introduced the industry had developed to such a point that there was an exportable surplus nearly all the year round in some part or other of Australia. So great is the range of climate throughout Australia that the butter export season now extends throughout the entire year. The result was that no State, even though it had not an exportable surplus, could get

much above export parity rates for its butter, because the local price was limited by that at which the nearest exporting State was able to land its butter in its neighbor's market.

Some years ago the position had become acute. The dairymen were paying Australian prices for everything they used in their homes and on their farms, and these prices, due largely to our fiscal policy and artificial living standards, are 25 to 50 per cent. higher here than in Great Britain. Thus the dairymen were paying more than 25 to 50 per cent. above world prices for what they had to buy, and were receiving 20 per cent. less than world prices for what they had to sell.

EXPORT PARITY.

Export parity rates means considerably less than world prices. That point is seldom grasped by economists. Export parity rates are world prices, less all costs incidental to transporting goods, perhaps 12,000 miles, less loss from deterioration in transit, and less insurance and other charges. Before this marketing scheme came into operation export parity prices were 2d. to 3d. per pound less than world rates. The dairyman received this reduced price, not only for the butter he exported, but also for what was sold in the home market.

When world prices collapsed about six years ago the position of primary producers in Australia became very serious, as the policy of high tariffs and high labor costs made it impossible to reduce costs of production to correspond with the continual downward drift in prices of primary products. The process of deflation in values of butter is illustrated in the following comparison of average prices of Australian choicest quality butter in London during recent years:—

	Per cwt.	
	s.	d.
1921	285	8
1925	180	8
1928	165	0
1929	171	0
1930	153	5
1931	110	0
1932 (first six months)	100	0

When the heavy decline in London butter values definitely set in, it became imperative to assist Australian dairymen and as, for political reasons, it was impossible to secure drastic revision of tariff duties and labor costs, it became urgent to find some method of affording quick and substantial relief. Many schemes were suggested, mostly involving complicated and controversial legislation and expensive organisations, but at last the Paterson scheme was formulated, and was soon recognised as the only practical and inexpensive way of rendering immediate and material assistance to producers.

The Paterson scheme is a purely voluntary one on the part of the producer; it is the farmers' own scheme, but the farmers must be loyal to one another, and its success depends entirely upon all Australian butter factories without exception contributing the levy of 1¾d. per pound on all butter manufactured, so as to enable the export bounty varying from 2½d. or more per pound to be paid, for it is only by the payment of these bounties that Australian butter prices can be raised correspondingly above London parity prices. By securing these higher prices on all butter consumed within the Commonwealth, factories are enabled to pay suppliers at least 2d. per pound more for butterfat than could be paid without the scheme. Taking an average production per annum of butterfat per cow at, say, 250lbs., this extra payment by factories represents an increased return per cow per annum of £2, which for a herd of 50 cows amounts to a total increase in annual income of £100, without the slightest increase in the dairy farmer's cost of production. In the case of very many producers, this additional income means a small profit in place of a loss on the year's returns.

Since its inception, the Paterson scheme has actually placed into dairymen's pockets millions of pounds in hard cash at practically no cost for its successful administration. It is obvious, therefore, that it is of supreme importance to dairy farmers throughout Australia to have the scheme maintained. It would be disaster to the dairying industry if the Paterson plan broke down.

THE LEVY.

Under this scheme a levy of 1¾d. per pound is voluntarily paid on every pound of butter produced, and that goes into a fund from which the bounty is paid on butter exported. It may be asked what advantage is derived from that? It certainly looks, on the face of it, like robbing Peter to pay Paul—as if the dairymen were taking money out of one pocket and putting it into another. In practice, however, that is not so. The direct result of the payment of an export bounty is that automatically, without any regulation, or compulsion, or legislation, the local price through the operation of an economic law rises to the level of the export price, plus the amount of the bounty paid.

It cannot be otherwise. It is a case of making use of an economic law instead of fighting it.

Had the butter industry tried to fix an arbitrary price for the local market, that price could only have been maintained by setting up elaborate machinery to compel every butter factory to take its fair share of both the export and local markets. That would have been a very difficult undertaking, and the administration costs would have been greater per dairyman than 9d. per annum.

During the past year, ending June 30th last, the total production of butter in Australia (excluding that of Western Australia, and also excluding the production of farm or dairy butter) was approximately 161,000 tons for the Commonwealth, whilst the approximate export for the same period was 92,000 tons for 12 months ending June last. This is a very big advance over production and export of the past season, which was 72,000 tons approximately exported for 1931.

Taking the levy of 1¾d. per lb. on butter manufactured, on 170,000 tons it would pay a bonus of 3d. per lb. on an export of 98,000 tons.

I purposely draw attention to this fact, because it has been said that the scheme will soon become useless.

This is not quite true in fact, as the levy of 1¾d. could be increased, and it would enable the 3d. bonus to be continued and will give in net results a substantial benefit to the dairying industry.

My contention is that until such time as all Australian industries are prepared to sell their productions at export parity rates, and all other industries in Australia are on a purely competitive level, we must insist on keeping the Paterson scheme going in the interests of dairymen, who, as a matter of fact, are at a dead end in high tariff legislation, and are quite unable to pass on the increased cost of production with which they are at present burdened.

RESOLUTION.

During the discussion which followed Congress decided, at the instance of the Redhill Branch, "That cream should receive better attention when delivered to railway stations." Delegates voted against resolutions from the Frayville Branch, "That the Dairy Act be amended" and "That cream be tested for commercial butter instead of butterfat."

MAXIMUM BREEDING.

The first essential is to resume breeding for quality with all possible haste. For the time being we are not in a position to discriminate to any great extent, owing to limitations both regarding mares and sires. Allowing 40 per cent. as an estimate of the percentage of mares of the total number of horses in the State, we have approximately 73,000 mares of a kind from which to breed, and with a further allowance for light horses included in that number, there would probably not be more than 70,000 mares. It is certain that many of these mares will never again carry a foal, neither have we sufficient sires to cover them. In the absence of official figures since 1920-21 it is estimated the number of draught stallions would not exceed 500. Therefore we are limited in discrimination a great deal in breeding where sires are available until such time as numbers are considerably increased, both for mares and sires, and it is evident that with the best possible effort it would take 10 years to restore the numerical strength to 250,000 without fairly heavy importations from outside.

QUALITY.

During the accomplishment of that objective of 250,000 horses there must be a growing attention to quality of breeding. With the exception of a few years prior to and during the war, our exports have not exceeded the number of importations. But with climatic conditions so admirably adapted for horse breeding, we should endeavor to obtain a standard of breeding which will enable us to secure a reputation capable of attracting export business. We have not achieved average quality to compare with the horses of New Zealand or even Victoria, and I see no reason why such should be the case. It is of the utmost importance that we exercise care and judgment in the selection of a stallion, and see that he is possessed of no hereditary weakness, of sound constitution, and true to breed. In this respect it would be of material advantage if all stallions were registered subject to a certificate of soundness from a Government Veterinary Officer. The fees collected from this source should be earmarked as a special fund to be used as subsidy within the industry, to which I shall refer later.

METHOD OF ATTAINMENT.

To suggest methods of improved breeding with due consideration to both quantity and quality, which could generally be accepted and applied, is a problem requiring a great deal of consideration in detail. In a paper given at our local Branch of the Bureau some 12 years ago I introduced co-operative ownership of entires. There are difficulties I admit, there is the question of responsibility, care of the animal, and efficient service. We saw all the difficulties in the scheme, and there it ended, and we continued to rely on the initiative and enterprise of a few horse lovers, however inefficient, and we have reached a crisis. Nevertheless, I am pleased to learn that co-operative sires have been working successfully, in spite of the drawbacks which may exist, and but for them the position would be worse. The question of sires has recently received attention quite frequently at Agricultural Bureau District Conferences, and the usual recommendation has been to the effect that Government should subsidise stallions on the same basis as it subsidises pedigreed bulls of good milking ancestry. It is overlooked that bull subsidies are defrayed from the accumulated licence fees of all the bulls of the State, and that whilst bulls are many, and individual subsidies relatively moderate, the reverse would be the case under either head for stallions.

Another objection to the proposal is that a stallion expected to travel the district should be in the hands of a specially qualified man, and whilst men of this type are to be found in some districts they are not common, nor, as a rule, can they afford to neglect their own farms for the benefit of their neighbors.

PROFESSOR LOWRIE'S SCHEME.

The Advisory Board of Agriculture realised the importance of sufficient and suitable sires, and appointed a small sub-committee to go into the matter. We came to the conclusion that the scheme proposed by Professor Lowrie in 1911 with possible modifications would give better results. Briefly his proposal involved the forming of horse-breeding societies, which were to be subsidised through 50 per cent. of the totalizator percentages being earmaked for that purpose.

The nuclei of these societies may be the Agricultural Bureau, Show Society, or even a committee of farmers in any district. The scheme involved a Government subsidy of £2 for every £1 raised by the society, with a maximum subsidy of £200. It did not, however, involve the purchase of a stallion for local use, but the offering of adequate moneys and fees in order to induce owners of approved sires to travel the district in which the horse-breeding societies were formed. The suggestion was to pay a fee at service, and a further sum to be paid by the society according to the number of foals left, at a given sum per foal. Such a scheme has much to recommend it, and should prove acceptable to both farmers and sire owners if the subsidy were obtainable. It is a matter of vital importance to the State, and which the Government might assist, but we realise that on financial assistance the Government cannot be approached to-day.

The matter of collecting an amount to provide subsidy would have to be through the medium of a tax which could only be applied fairly to horses at a given amount per head on horses within the counties. This means of providing the necessary revenue would not fall very heavily on the industry concerned, and with registration fees for draught entires earmarked for the same purpose would possibly not exceed 1s. per head.

The difficulty in collecting the tax without evasions and doing so economically rather prejudices such a scheme, and we have not reached finality in a recommendation applicable to the State as a whole.

CONCLUSION.

It may be said that I have failed to put up a complete proposal which will achieve the objectives set out in the title of the paper. To some extent that may be true, but if any impression has been created in the minds of those assembled of the pressing need for greater diligence and energy being applied to horse breeding, with a view to safeguarding and improving the present rate of rural production, our time has been well spent. I consider any upward movement in horse breeding throughout the State depends upon some such scheme to improve the methods of draught stock breeding.

TRUSTEESHIP WITH SECURITY

RAPIDLY INCREASING NUMBERS OF PERSONS ARE
ENTRUSTING THEIR ESTATES TO THIS COMPANY

WHY?

BECAUSE they do not have to fear loss of assets.
BECAUSE they know the Company is impartial and will live to complete its duties.
BECAUSE the administration of Estates in the care of the Company is carried out promptly, efficiently, and economically.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

FORTY-THIRD ANNUAL CONGRESS.

The Forty-third Annual Congress of the Agricultural Bureau of South Australia was held in the Way Hall, Adelaide, on September 12th, 13th, and 14th, and the record attendance of delegates can be taken as an indication that interest in the work of the Bureau is being maintained.

Congress was opened by His Excellency the Governor-General, Right Honorable Sir Isaac Isaacs, P.C., G.C.M.G., on Monday, September 12th, at 8 p.m. Mr. H. N. Wicks (Chairman of the Advisory Board of Agriculture) presided, and amongst others present were Hon. S. R. Whitford, M.L.C. (Minister of Agriculture), Professor A. J. Perkins (Director of Agriculture), Members of the Advisory Board of Agriculture, and officers of the Department of Agriculture and the Waite Research Institute.

The following delegates attended:—*Alawoona*—B. L. Finey (4), T. Willson (4); *Aldinga*—G. Sheriff (3); *Allandale East*—H. Kerr (5), R. Kerr, jun. (6); *Angaston*—Wm. Sibley (2), Wm. Patching (3); *Arthurton*—Geo. Hicks (0), S. Henderson (3); *Ashbourne*—K. M. Horwood (0), C. J. Pitt (3); *Auburn Women's*—Miss Dennison (4), Mrs. J. Morcom (4); *Balaklava*—A. F. Smart (5), W. P. McPharlin (5); *Balhannah*— — Norsworthy (2), H. Rollbusch (3); *Balumbah Women's*—Mrs. A. Ellis (5); *Belalie Women's*—Mrs. M. Bailey (5), Mrs. C. R. Hawke (5); *Belvidere*—H. A. Eckert, jun. (4), M. S. Pearce (5); *Berri*—A. G. Jarvis (4),A. W. Magarey (4); *Blackheath*—H. Paech (5); *Black Springs*—J. M. Howard (3), Roy Turner (4); *Blyth*—H. A. Zweck (2), L. C. Mugge (2); *Bowhill*—M. A. Cockshell (0), A. J. Spry (2); *Boors Plains*—T. A. Stanway (2), K. K. Queale (2); *Borrika*—H. S. Green (6), C. S. Wardley (2); *Brentwood*—E. E. Twartz (0), J. Honner (1); *Brinkley*—W. H. Schubert (0); *Brinkworth*—H. E. Ottens (3), H. E. Wundke (3); *Brownlow*—A. O. Steinborner (4), C. A. Materne (4); *Buchanan*—W. J. Armstrong (3), L. V. Bell (0); *Bugle*—E. T. Smith (0), J. C. Scott-Todd (1); *Bundaleer Springs*—T. Cleggett (4), M. J. Cronin (3); *Bute*—E. H. Ebsary (6); *Butler*—A. H. Pfitzner (4); *Caloa*—J. H. Kelsh (4), F. L. Roberts (3); *Caliph*—J. W. Burnett (2), W. H. Todd (3); *Chandada*—R. R. Loveday (0), R. H. Ross (3); *Cherry Gardens*—B. B. Ternan (1), R. Jacobs (1); *Clanfield*—L. Orwell (4), S. Orwell (3); *Clare Women's*—Mrs. J. C. Dux (1), Mrs. A. H. Rogers (2); *Clarendon*—E. H. Harper (0), T. B. Brooks (3); *Cleve*—F. G. Hauschild (5), A. V. Preiss (3); *Collie*—H. Shipard (4), D. J. Gunn (4); *Coomandook*—F. E. Ballard (4), W. R. Trestrail (3); *Coonawarra*—W. L. Redman (5), E. G. Allder (5); *Cungena*—C. L. Ayliffe (5), S. H. Bennie (5); *Dudley*—A. G. Telfer (2). E. Dall (2); *Elbow Hill*—John Rehn (4), W. T. Cooper (4); *Eurelia*—M. P. Dinon (3), E. H. Hall (3); *Eurelia Women's*—Miss R. Kildea (4), Mrs. E. P. Wall (4); *Everard East*—F. C. Hughes (5); *Finnis*—M. Llewellyn (2); *Frayville*—C. R. Banks (4), S. A. Bretag (4); *Gawler River*—E. Leak (0); *Geranium*—E. G. Williams (0), L. S. Prouse (5); *Gladstone*—J. W. Prior (3), C. R. Bennett (3); *Gladstone Women's*—Mrs. E. C. Pritchard (4), Miss M. J. Sargent (4); *Goode*—C. P. Linke (5), J. H. W. Cooper (5); *Goode Women's*—Mrs. D. Fagen (5); *Green Patch*—C. J. Whillas (4); *Greenock*—E. Keller (5), E. J. Helbig (3); *Gumeracha*—W. L. Hanna (0), John Porter (0); *Hanson*—C. P. Turner (3), W. J. Woollacott (1); *Hartley*—T. G. Jaensch (2), W. J. Lawton (2); *Hindmarsh Island*—C. F. Kightley (3); *Inman Valley*—R. J. Gregory (3), H. L. Lush (4); *Jamestown*—W. C. Glasson (3); A. J. Symonds (4); *Jervois*—E. Schultz (4), M. Wilkin (4); *Kalangadoo*—R. G. Messenger (5); *Kalangadoo Women's*—Mrs. L. R. Davies (4), Mrs. R. G. Messenger (5); *Kanni*—F. W. Woodhead (3), H. E. Krohen (2); *Kapinnie*—Chas. Luckraft (2); *Kalyan*—R. E. R. Lang (6), H. R. Norman (1);

Kangarilla Women's—Mrs. J. White (3), Mrs. G. Thorpe (3); *Kareultaby*—J. A. Freeman (3), A. W. Rutherford (4); *Keith*—T. A. Dickson (5), A. M. Densley (3); *Ki Ki*—O. Blucher (5), F. Griffiths (2); *Kilkerran*—B. A. Koch (3); *Kongorong*—C. T. Atkin (4), F. C. Caine (4); *Koolunga*—J. H. Button (3); *Koonunga*—J. Mickan (3), A. Hermann (4); *Koppio*—V. W. Gardner (5), B. G. Low (4); *Kulkawirra*—D. A. Oakley (2), O. N. Fitzgerald (2); *Kyancutta*—J. J. Dyke (6), M. M. O'Brien (5); *Kybybolite*—W. Staude (1), D. Quinn (2); *Lameroo*—J. L. Koch (5), C. R. Eime (5); *Langhorne's Creek*—N. S. Wheller (5); *Laura*—F. Neate (4), Chas. Amey (3); *Laura Bay*—E. D. Barnett (5), W. L. Edson (5); *Light's Pass*—A. J. Summers (5), T. W. Roenfeldt (2); *Lipson*—C. J. Partington (2); *Lone Pine*—E. R. Hentschke (4), S. M. Turnbull (4); *Lone Gum and Monash*—E. N. Hall (2), H. March (2); *Lyndoch*—W. H. Lawes (1); *Macclesfield*—Ken Bowen (0); *McGillivray*—E. C. Seager (3), J. N. Wood (2); *Maltee*—J. Bassham (6), E. Schwarz (5); *Mangalo*—M. Hannemann (3), A. Turner (4); *Mangalo Women's*—Mrs. A. E. Lathlean (3), Mrs. F. Coles (3); *Marama*—T. A. Hailes (5), H. L. Whitford (2); *McLaren Flat*—C. Robertson (2), Geo. Connor (1); *McLaren Flat Women's*—Mrs. K. Warrenn (0), Mrs. C. Robertson (5); *Milang*—H. Matheson (3), A. Matheson, jun. (4); *Millicent*—R. Hateley (5), C. Hutchesson (5); *Millicent Women's*—Mrs. P. Sullivan (5), Mrs. S. D. Williams (5); *Miltalie*—F. Coles (6), J. P. Story (4); *Minnipa*—S. C. Billinghurst (3), D. V. Kitto (4); *Modbury*—W. H. Pitman (1), L. J. Wicks (0); *Monarto South*—L. M. Thiele (4), P. B. Frahn (6); *Moorlands*—R. Nicholls (5), R. R. Wilmshurst (5); *Moorook*—S. Perkins (4), E. A. Liddicoat (2); *Morchard*—M. A. Brown (5), B. S. McCallum (5); *Mount Barker*—W. T. Stephenson (2); *Mount Bryan*—A. A. Jefferies (5), W. H. Quinn (3); *Mount Compass*—M. Jacobs (0), B. Proctor (3); *Mount Gambier*—A. J. Hemmings (4), G. T. Gurry (6); *Mount Hope*—J. H. Vigar (4); *Mount Pleasant*—P. S. Davey (0), F. R. Ayers (0); *Mudamuckla*—V. V. Brandon (2), E. Whyborn (5); *Mundalla*—L. M. Dinning (6), F. V. Trenorden (3); *Murray Bridge*—A. Wells (5), F. Lehmann (2); *Murraytown*—E. B. Pitman (5); *Myponga*—C. A. Martin (3), J. J. Muller (2); *Nantawarra*—K. W. Young (3); *Narridy*—T. R. Welbourn (3), H. B. Cox (2); *Narrung*—P. W. Thacker (6); *Nelshaby Women's*—Miss R. I. Haines (4), Miss A. M. Lawrie (4); *Nelshaby*—E. H. Williams (5), F. Desilver (5); *Netherton*—F. Hosgood, sen. (5), C. P. Wilkin (4); *Nunjikompita*—P. A. Luestner (4); *Nunkeri*—J. R. Ling (0); *Overland Corner*—C. C. Bartel (4), H. A. Loffler (5); *Owen*—A. J. Freebairn (3), S. Lacey (4); *Palabie*—E. H. Rashleigh (5), A. Miller (6); *Parilla*—A. W. Welden (5), S. A. Gregory (5); *Parilla Women's*—Mrs. L. Foale (2), Mrs. A. W. Welden (4); *Parilla Well*—V. E. Venning (3), W. H. Simpson (4); *Parilla Well Women's*—Mrs. E. C. Slater (5), Mrs. M. S. Davis (4); *Parrakie*—W. J. B. Halliday (4), W. Watts (5); *Parrakie Women's*—Mrs. M. J. White (6), Miss Hamilton (5); *Paruna*—A. C. Webb (3), A. A. Petch (1); *Paskeville*—M. K. Lamming (5), F. J. Rundle (5); *Penola*—H. B. H. Richardson (2), F. W. Hinze (5); *Penola Women's*—Mrs. F. J. Kidman (3), Mrs. W. A. Clifford (6); *Penwortham*—A. T. Duke (6), J. H. Richardson (1); *Petina*—H. H. Howard (3), W. E. Stone (2); *Pinbong*—H. B. Scholz (5), H. M. Johnson (6); *Pinkawillinie*—B. Hudson (4), S. C. Johnson (4); *Pinnaroo*—A. F. Young (3), C. R. Mattiske (5); *Pinnaroo Women's*—Mrs. W. B. Davis (3), Mrs. A. T. Hawthorne (5); *Port Elliot*—F. C. Keen (3), J. P. Colebatch (5); *Pygery*—E. H. Edmonds (4), B. G. Heath (5); *Quorn*—O. C. Noll (0), C. J. Easther (4); *Ramco*—Robt. Stanley (3), J. Boehm (0); *Redhill*—J. V. Dundon (3), H. J. Crouch (5); *Rendelsham*—F. E. White (6), V. A. Smith (4); *Renmark*—M. B. Geneste (3); *Richman's Creek*—W. J. Kelly (3); *Roberts and Verran*—R. A. Paxton (4), J. T. Hancox (4); *Rosedale*—S. Simcock (1); *Rudall*—W. Wake (4), R. M. Crabb (3); *Saddleworth*—F. W. Colman (3), A. J. Marrett (1); *Saddleworth Women's*—Mrs. F. Coleman (4), Mrs. G. Crawford (3); *Sandalwood*—W. R. Cairns (5); *Scott's Bottom*—J. C. Blakley (0), O. Boeckers (0); *Shoal Bay*—C. Milner (3); *Wallala*—W. R. Baldock, jun. (4), M. R. Nottle (0); *Wandearah*—W. C. Slater (5), J. S. O'Shaughnessy (5); *Warcowie*—S. A. Sweet (5), G. T. Hilder (2); *Warramboo*—E. J. D. Oswald (4), E. Adams (5); *Warramboo Women's*—Mrs. F. Chilman (4), Mrs. C. Deed (6); *Wasleys*—E. W. Day (1), W. C. Toll (0); *Wasleys Women's*—Mrs. F. Sanders (2), Miss G. George (4); *Watervale*—G. Holder (4), W. Hamp (6); *Wauraltee*—A. W. Kelly (1), A. V. Mitchell (4); *Weavers*—J. A. Bridges (2), H. W. Cornish (3); *Wepowie*—D. M. Grogurke (4), D. Crocker (4); *Wilkawatt Women's*—Mrs. W. Neville, sen. (5), Mrs. J. Steer (5); *Williamstown*—D. P. Gordon (2), Syd. Coleman (4); *Williamstown Women's*—Mrs. G. Hammat (6), Mrs. E. Coleman (5); *Willowie*—H. T. Hughes (5), A. Crisp (6); *Wilmington*—M. Christopherson (3), Chas. Cole (5); *Windsor*—A. D. Prime (0); *Wirrabara*—H. W. Hollitt (4), Ron. Bowman (4); *Wirrilla*—R. F. Kelly (4), A. E. Scarfe (6); *Wirrilla Women's*—Mrs. R. Woods (1), Mrs. W. R. Jones (2); *Wolseley*—H. C. M. Pilgrim (4), A. Grosser (5); *Wudinna*—Wm. A. Dubois (5), C. W. Johns (5); *Wynarka*—H. Rawlins (5), M. N. Blacket (6); *Yadnarie*—F. W. Jericho (4), J. E. Quick (4); *Yaninee*—G. P. Roe (4), J. L. Roe (4); *Yantanabie*—L. N. Nield (0); *Yeelanna*—R. R. Wilson (6), Geo. Aird (5); *Yurgo*—J. Bullen (5), M. E. Walker (4); *Yurgo Women's*—Mrs. L. Hopgood (3), Mrs. H. Sanders (5).

The figure after each delegate's name indicates the number of sessions attended; 6 being the maximum.

OPENING SPEECH BY HIS EXCELLENCY SIR ISAAC A. ISAACS (GOVERNOR-GENERAL).

I very much appreciate the honor of being asked to deliver this opening address. I do so for two reasons: one is that as it is obviously impossible for me to visit every important centre of production in Australia, it is a very welcome sight indeed to me to see so many representatives of producers and earnest students in the science of agriculture gathered together. It enables me to give to you all and to those whom you represent in your home towns the message of His Majesty's constant and strong personal interest in your welfare and in the work that you are doing in developing your part of the Empire, and to tell you how delighted he always is to hear of the success and progress of his people. The other reason is that I recognise as well as you do the public importance and advantage of such a Congress as this.

Agriculture plays such a great part in our national life, even if we look upon it as confined to its own special domain, and still more when we remember how intimately it is connected with the other two branches of industry, the pastoral and the manufacturing industries, but it is very hard indeed for anyone to over-estimate its claim on our attention. Now, if this were a conference on human progress it would be very interesting indeed to start with the arresting fact recently given prominence by an eminent scientist, an Australian, by the way, Professor Elliott Smith, which I recently read. He says: "Civilisation began when man ceased to be a mere food gatherer and became a food producer—a farmer, who cultivated cereals and bred cattle." He says: "That the presence of a natural crop of barley on the banks of the Nile was, in all probability, the predisposing factor in starting that vast revolution in the affairs of mankind which led on to the creation of civilisation, because it allowed mankind to settle down in one place and give up his nomadic life; it allowed him to multiply, to commence those arts and sciences which gradually have led up to the present day culture and refinement.'' And that was somewhere about 6,000 years ago.

The astonishing fact to me is that although agriculture itself became known to mankind 60 centruies ago, yet scientific or intensive agriculture is not yet quite 100 years old. Indeed, as you know, in some of its essential features, like the production of our great wheats, it is little more than 30 years old. There are two facts which always appeal to my mind and which show the wonderful advances made in late years. The one is—and I do not know whether this has ever struck your minds or not—the old table of Troy weight we learnt at school, and the other is, for instance, Farrer's Federation wheat. Troy weight tells of 24 grains in one pennyweight. That has a history. In Saxon times, before money was coined as it is now, and milled, people used to clip a little bit off the silver penny, and if any one wanted to know whether he was tendered his full weight for his goods, the Saxons made a law that if you put the penny in one scale and put the 24 grains of wheat, dried in the ear, on the other side, that was a test whether it was a proper pennyweight. In Farrer's Federation wheat we see the triumph of scientific hybridisation. It shows the wonderful advance being made in one direction of agricultural science, and we know that it is the last 50 years in which the science of agriculture has embraced almost every activity that goes to make farming a successful avocation and the farmer a prosperous and cultured and self-reliant citizen. It does so much to convert farming from being a mere hazardous calling to being a comparatively reliable enterprise. Indeed, experiments in soils and fertilisers, in conservation of moisture, in improvements of plants, in diversification of crops, in mixed farming, in herd testing, and in farming practices generally, have transformed, and are daily transforming the whole science of agriculture. And I think that South Australia is very fortunate in having a Department of Agriculture that is alive to all of these things. And it is fortunate, too, in having a Bureau of Agriculture so constituted that we are able to focus, so to speak, at one place, as here to-night, so much energy, enthusiasm, experience, and educational fervour from all parts of this State. This Congress is not only likely to be of great value to the State of South Australia, but, indeed, to the whole Commonwealth. I hope it will be one of great success. I trust that you will all be able to look back to this Congress, not only as a step in advance in the science of agriculture, but also as a signal aid to the development of our vast and noble Empire to which we are all ready and eager to render loyal and useful service.

At the instance of Mr. A. J. Cooke, seconded by Mr. J. B. Murdoch, a hearty vote of thanks was accorded His Excellency.

ADDRESS BY THE MINISTER OF AGRICULTURE (HON. S. R. WHITFORD, M.L.C.).

This is the third occasion on which I have had the pleasure of addressing you at the opening of your Conference, and whilst we must all regret that hitherto we have met under a cloud of intense economic depression, we can take comfort from the thought that the seasons have begun to smile upon us again, and that to-day we can anticipate that, with moderately favorable spring conditions, last year's record wheat production of 48,000,000bush. should be exceeded in the current season.

In this connection I cannot help expressing my personal admiration for the plucky fight put up by primary producers during the recent difficult times. It is well known that two years ago the Commonweath as a whole found itself suddenly faced by a financial position of considerable difficulty, from which honorable extrication did not seem possible except by rapid accumulation of overseas credits. Unfortunately, towards that end there was little apart from primary products that could be exported to advantage from Australia; unfortunately, too, both current and prospective prices of these products were abnormally low; and it follows that if overseas commitments were to be met considerably increased rural production had become a national necessity; hence an urgent call for maximum rural production that circumstances permitted was issued by the Federal authorities. And loyal and thorough has been the response of South Australian producers in spite of the prospect of disastrously low prices. In 1930-31 our farmers put in a record area under wheat—4,180,000 acres—but the season proving unfavorable only a moderate yield resulted; nothing daunted, our farmers sowed only a slightly reduced area in 1931-32, and had the satisfaction of harvesting a record return of over 48,000,000bush. In 1931-32 our butter exports rose from 1,097 tons to 3,303 tons; our cheese exports from nil to 400tons; our eggs in the shell from 773,000doz. to 2,026,000doz.; our fat lambs from 20,821 to 136,000; our wines from 1,830,000galls. to 3,035,000galls., and so on. We have here a record of which our primary producers have every reason to be proud; and much is it to be regretted that unprecedently low world prices should have robbed them of the full reward of their efforts.

Let us not forget, however, that the export of much of this rural produce would not have been economically possible but for our adverse exchange rate, which has had the effect of raising local prices above world parity to the extent of 25 per cent.; had exchange been near normal, and exports curtailed accordingly, our home markets would have been completely demoralised, and the position of rural producers parlous in the extreme Hence, in the interests of primary production, and coincidently of the State and Commonwealth as a whole, it is much to be hoped that this adverse exchange rate will be maintained until such time as world prices of rural commodities shall have attained to a more normal level.

OTTAWA.

Whilst on this subject our thoughts turn naturally to the Ottawa Conference and the probable influence of its decisions on the export of our primary products. In this connection it is perhaps as well to remind ourselves that without full official details it may be dangerous to jump to hasty conclusions; and even with complete information on the subject it will be very difficut to forecast with any degree of accuracy what are likely to be the ultimate effects upon international trade of a series of trade restrictions conceived with the set purpose of confining the former to certain well defined channels. Factors influencing the flow of international trade are many and elusive; nor does it necessarily follow that they will prove altogether amenable to the pressure attempted from Ottawa. And in any case, whatever the ultimate facts, competition—the soul of trade—will continue to rule notwithstanding preferential market treatment. Other Dominions, in closer proximity to the British Isles, will be our trade rivals for corresponding goods. In the immediate past, for instance, British annual imports of wheat have averaged in the neighborhood of 194,000,000bush.; of this total, Canada—with freight charges about one-half of normal Australian charges—has supplied 62 millions, and Australia 24 millions only. Hence, it seems probable that Canada may be able to benefit from the 2s. preferential duty per quarter at the expense of the United States, with similar freight charges and normal exports to Great Britain of 52,000,000bush. per annum. Australia, on the other hand, with its prospective exportable surplus of 150,000,000bush. is not likely to displace Argentenian normal exports of 42,000,000bush., because after due allowance for British preference Argentina would still retain an advantage of 3d. a bushel from freight. I know that I have laid myself open to the accusation that I have rushed headlong into one of those hasty conclusions that I deprecated in my opening remarks, and whilst repentently admitting the fact, I can only add that none more than I will be pleased, should events prove me eventually to have been in the wrong

The fact of the matter is that, as suppliers of surplus foodstuffs, we are wrongly situated from the geographical standpoint; we are further off from the densely populated food importing countries than any of our trade rivals, and our shipping difficulties and cargo rates are correspondingly greater. Hence, we start business with a heavy economic handicap, and if, in spite of this, we wish to succeed, less than any other exporting country, can we afford to sin against the following trade canons:—

(1) Attention to quality in all products exported;
(2) Strict maintenance of uniformity in grade;
(3) Truthfulness of description; and
(4) Attractiveness of external get-up.

I am aware that I am on one of my pet hobbies now, but I know that I shall be excused for repeating myself when I state my earnest belief that strict adherence to the highest quality possible in all our exports can alone help us to overcome adequately our geographical disadvantages. I trust, too, that should at any time any of you find your exportable commodities turned down as unsuitable for export, you will realise that such measures are taken in the interests of Australian trade generally, which it is of national importance to maintain at the highest possible level. Temporary gains from the sale of inferior articles are to be deprecated, as ultimately they can have but one effect, namely, branding Australia as a country of shoddy goods, and condemning us permanently to unprofitable price values.

But if, for the sake of argument, we assume that preferential treatment on the British markets will realise our wildest imaginings—and eventually I hope that it may be so—there is one point that we should ever keep steadily before us, nor should we allow those in control of affairs of the nation to forget it, namely, that initial success is no guarantee of permanence, or even of lengthy life. There can be no permanency of trade where the advantages are all one way; permanency of trade is essentially dependent upon reciprocal advantages. We have wrung from Great Britain a series of preferences for our exportable goods in what, from press reports, appears to have been a close-fisted chaffering match, rather than the open-handed conference, which the Prime Minister of Canada is said to have anticipated. Beyond a few vague statements we are as yet without definite information as to what Australia has offered in return for preferential treatment on British markets. A general lowering of the tariff wall coupled with effective British preference appears to have been hinted at. If this be so, much will depend upon the local interpretation eventually placed upon these offers; unfortunately, the all but prohibitive tariffs at present in force may tempt us to satisfy the letter whilst avoiding the spirit of our Conference commitments. Heavy scaling down of our tariffs can alone, in my opinion, satisfy both our apparent commitments and our general requirements as a nation. The immediate effect of such a policy should be the gradual development of a steady flow of imports from Great Britain in payment for corresponding exports from Australia to Great Britain. The eventual benefits to us from this reciprocal flow of trade should be considerable; vessels required for loading our exportable commodities would no longer be forced to reach our shores on ballast, and freight rates to Great Britain would be correspondingly reduced; increased returns from Customs duties should render Federal direct taxation unnecessary; our costs of living would fall; all of which would be reflected in all round reduction in costs of rural production, and we should then find ourselves definitely in the position to compte effectively on any of the markets of the world.

If results such as these can eventually be secured from the deliberations recently held at Ottawa, we shall all agree that the Conference will not have been held in vain. It is perhaps necessary to add here that preferential access to the vast British markets, which ostensibly aims at lessening on our behalf the competition, both fair and unfair, of international trade on these same markets, does not necessarily ensure to us thereon prices better than the world parity of the day. The latter, as in all times, must continue under the governance of world wide conditions, which we trust may soon lead to progressive improvement Moreover, apart altogether from possible retaliatory measures against Great Britain or the British Empire, the attempted exclusion of foreign interests from British markets must inevitably expose us to keener competition on foreign markets which we might find it necessary to approach. Finally, I shall again stress the fact that the benefits we anticipate from the Ottawa preferences are likely to be very short-lived, unless from the outset we honestly recognise the essential mutuality of successful trade relationships, and determine to abide by our side of the bargain.

I wish next to make brief reference to the Roseworthy Agricultural College. This institution has recently had to face an extremely severe ordeal; and I feel certain that all those of you who were acquainted with its past record will have sympathised with it in its troubles. I am not, however, at present concerned with past difficulties; the Government believes that it has taken effective steps to prevent any future recurrence of them, and we shall leave the dead to bury their dead. We have placed the College under the control of a Governing Council, of which two members only are public servants; the Government appreciates very highly the public-spiritedness of those who have accepted seats on the Council, and feels confident that the future of the College can be safely left in their hands. I wish also to commend to you the new Principal—Dr. A. R. Callaghan—who has come to us from New South Wales with the highest credentials. He has already created a good impression on all those with whom he has been brought in contact, and I feel sure that in a very short time he will win back public confidence for the College.

And lastly, gentlemen, let me congratulate you all on the prospects of another favorable season. I know that the low price for wheat is still causing you anxiety. Last year the Premier and I tried hard to induce the Federal Government to impose a sales tax on flour, from the returns of which the wheat growers of Australia would have been paid a special bonus. We did not succeed, but eventually the Federal Government paid you a direct bounty of 4½d. per bushel, involving a loan of over three million sterling, interest on which has to be borne by the general taxpayer, and the principal of which will eventually have to be met from the same source. The sales tax would have entailed payment of niether interest nor principal, and in the circumstances we thought it better adapted to the existing financial position I can assure you that we have not forgotten you in the present season. If prices do not improve appreciably towards harvest time we shall take the matter up again with the Federal Government.

Mr. A. M. Dawkins moved, and Mr. P. J. Baily seconded, a vote of thanks to the Minister for his address.

ADDRESS BY THE CHAIRMAN, ADVISORY BOARD OF AGRICULTURE (Mr. H. N. WICKS).

When we met here last year we were passing through the worst period ever experienced by the majority of those present, and the outlook was such as to render much hope in the future well nigh worthless. On that occasion I stated that the best advice I was able to give was to hang on to the last, and that even the record depression would possibly give way to a record time of prosperity and plenty. It is indeed gratifying at the end of such a short period as 12 months to be able to state that there are tangible and definite indications that we have passed the critical stage, and that the turning point, if not actually with us, is indeed in sight, and I repeat here that I am of opinion that the lessons learnt during this time of trial may eventually lead us to that record term of prosperity which we are all looking forward to at this period. Let us hope that when this period does arrive we may utilise it not merely for selfish ends, but having in view those who have to follow us, and I hope the desire to make the Commonwealth a safer and saner place for those future generations will be the first desire of everyone. The great fundamental lesson which has been forced home to us, both from an individal and Commonwealth standpoint, is the fact that neither the individual nor the nation can practise the policy of earning a pound and spending 21 shillings indefinitely without having some day to face a day of reckoning, however much deferred. If we can absorb this vital truth and act upon it then the depression, if it has taught us the force of this, will not have been in vain

The encouraging reports on the wheat and wool markets inspire us with confidence for the future, and we trust that the present prices will increase still further, so that the financial stability of the State and the individual may be quickly restored. Our export trade in dairy produce and eggs has shown us that an increased production of these commodities is warranted, and, having obtained a firm footing on the overseas markets, we should strive not only to maintain it at the present extent of trade, but to continue to increase our hold on those markets which offer an illimitable scope for our produce.

Both dried and fresh fruit have continued to do their quota in helping the finances of the State, and although some of the later shipments of apples were disastrous to growers, nevertheless the average season's operations must be classed as satisfactory, and the future is certainly hopeful, possibly more so since the Ottawa Conference.

PERSONNEL OF THE BOARD.

During the year the Board lost one of the most ardent workers on behalf of the producer through the lamented death of Mr. H. S. Taylor. Mr. Taylor's sound judgment and advice have been greatly missed by his fellow Board members. Intensely interested as he was in the welfare of the River Murray settler he devoted a large portion of his time and energy to the interests of other producers throughout the State. His place has been filled by the appointment of Mr. J. B. Murdoch, whose experience in connection with the marketing of dried fruits will be of immense value to the Board in dealing with problems not only of the fruit grower, but of the farming community as a whole.

LIFE MEMBERSHIP.

As a mark of appreciation of the work done on behalf of our organisation, the Board has conferred Life Membership to 30 members during the year. This distinction, however small, is, I am sure, appreciated by the Bureau as a whole, and when it is considered that the qualification of 20 years' service is required for this distinction, we must all realise that the Bureau could not have any greater mark of appreciation of its worth than to know that so many of its members have been actively associated with its operations for such long periods

BRANCHES.

Eight Branches were added to the roll during the year ended June 30th, and the total membership of the organisation was then 8,283, with 316 Branches. The interest in Bureau work has been well maintained, and many Branches have exhibited increased activity. Encouraging reports have been given by departmental officers on meetings at which the members have shown an outstanding interest in search of information, particularly on subjects which at one time were regarded merely as sidelines, but are now being looked upon as most important revenue earning operations of a farm.

There has been a marked improvement in the work of the Women's Branches. The number of Women's Branches has now increased to 29, and when it is recalled that most of these Branches have been established voluntarily and without any organised system of advertisement, it is evident that country women are realising the many advantages which may be obtained through the services of this institution.

CONGRESS AND CONFERENCES.

The largely attended Congress of 1931 was gratifying to all concerned, and I venture to think that the meetings arranged for you this year will be the means of making Congress more popular than ever, and that delegates will return to their Branches with the conviction that there is no neglect on the part of the Agenda Committee in keeping up the standard of agricultural education which the Congress affords.

In all there have been 17 Conferences held in various parts of the State during the year. Members have shown enthusiasm by their attendance and by the valuable material they have supplied for the respective Agendas. The value of a Conference cannot be overestimated, and I strongly advise all members to continue their interest in this sphere of Bureau work. Conference districts are formed with the main object of bringing together a group of Branches having similar agricultural interests. District Conferences, therefore, provide the only means for famers to meet for the purpose of discussing agricultural practices within their own limits of soil and climatic conditions. Every opportunity should, therefore, be taken by members to attend these gatherings not only for their own personal advancement but for the general welfare of their districts.

THE WORK OF THE PAST YEAR.

Many resolutions from Conferences have been forwarded to the Board for consideration. It has been the practice to advise the Branch submitting a resolution as to the action taken by the Board. Following a discussion at the recent Southern Conference the Board has now decided that after a Conference has been held this information will be given to all Branches in the Conference district concerned instead of to an individual Branch.

The Board has also adopted a new rule in respect to voting for the place of the next Conference. In future each Branch represented at any Conference will appoint one member to act as its representative, and the voting for the place of next Conference will be confined only to those representatives. This has been practised in some districts of recent years, and it has given general satisfaction.

With refernce to the resolutions of last year's Congress it will be noted that a Parliamentary Committee has taken evidence on the question of Bulk Handling, and it is hoped to publish a resume of the Committee's findings in due course. Matters dealing with taxation were brought under the notice of the authorities, and in the case of the sales tax on farm machinery, the loss of £140,000 per annum in Federal revenue, if the tax were removed, has been a barrier to any alteration in this legislation. Motor registrations have been reviewed, and it will be seen from the Agenda that this question will be again brought up for discussion at this Congress. The Bureau protested against the tariff, and it is expected that this protest will have some effect in reducing the burden which the farmer has to bear under our protective policy. The question of the use of producer gas for driving farm tractors has been placed before the Council for Scientific and Industrial Research, and we have been informed that the lack of funds has prevented that body from making further research into this matter. We have been assured by the Controller-General of Customs that the necessity for close supervision in order to ensure that the prescribed conditions relating to the size and quality of cornsacks has been strongly brought under the notice of the Collectors of Customs in the several States.

Inquiries were made in relation to the branding of wheat bags, and it was found that the policing of the proposed legislation would necessarily involve the Government in considerable expenditure which in times like the present could not be recommended.

The request that bales of binder twine be labelled showing description, weight, etc., has been taken up with the Chamber of Commerce, and it is proposed to bring this matter up again to see if some of the difficulties that at present stand in the way can be overcome.

The Board has not lost sight of the request for the abolition of the outward wharfage on primary products, and in relation to the annual subscription of Bureau members it has been explained to Branches that owing to the financial position no alteration in the existing conditions has been recommended. You will notice, however, that this question will also be again discussed at this Congress.

In regard to the prevention of fire in country districts the Board got in touch with all Branches with a view to impressing upon them the benefits that would be obtained by joining forces with fire-fighting organisations in their work of fire prevention and control.

The resolution of Congress relating to the suggested closing of country schools no doubt had some influence on the Government in maintaining these schools as in the past.

Among the many items which have been dealt with by the Board during the year the question of the sale of butter substitutes has had the consideration of the Government, and regulations under the Food and Drugs Act will come into force on November 1st, and these regulations should have some effect in protecting the dairying industry.

The National Council of Woolselling Brokers has given an assurance that the blue stripe in woolpacks about which many complaints were received would be eliminated as far as possible.

A deputation of Board members waited on the Minister during the year in connection with the Turretfield Farm, and the Government subsequently decided to continue the operations of this Farm for the purpose of raising seedwheat. As soon as the Department is in a position to offer reliable seed it is sincerely hoped that farmers of the State will, by purchasing seed requirements from the farm, show their appreciation of the Government's action in this matter.

Representations were made to the fertiliser companies with the result that there was an announcement last season that a cash discount of 5 per cent. would be allowed on purchases of superphosphate as well as an extra 1s. per ton for deliveries made during January and February.

Attention was drawn to the danger of introducing Phylloxera through the medium of fruit carried by passengers on steamers, and action was taken by the Phylloxera Board to safeguard fruitgrowers' interests by the destruction of fruit introduced in this way.

As a result of a resolution passed at the Wudinna Conference the General Manager of the State Bank intimated that his Board was prepared to consider applications for payment of wages to applicants' sons when actually incurred and payable in connection with the provisions of the Farmers Relief Act.

The Board decided to hold a special Conference in the interests of Branches associated with the dairying industry. This was held at Mount Barker, and was regarded as one of the most successful Conferences held throughout the year. Another Conference will be held next year in the same locality.

A further successful Conference was held for settlers on the irrigated areas along the River, and it has been decided to make this an annual function.

At the instigation of Branches the Board has recommended to the Minister that steps be taken to bring into operation a scheme of certifying seed potatoes on similar lines to that adopted in Western Australia.

Other items of interest are:—

A reduction in the commission charges on sales in country markets has been secured, and the rate is now 5 per cent. instead of 10 per cent. as in the past.

The Board has given its support to the request for raising funds for the purpose of investigating the thrips pest, and finally we are indebted to the Director of Education for this compliance with out request to make the school holidays in 1933 synchronise with the September Show, so that country parents may have a better chance of visiting the Show with their children.

There are many other investigations which are in progress, and the Board will do what it can to bring them into effect for the welfare of the farming community.

In concluding my remarks I desire to refer in brief to the estimable work which Branches have done throughout the year in connection with competitions, and to the assistance which members may seek from the instructional staff of the Department of

Agriculture, and in passing we extend our heartiest congratulations to Mr. A. M. Dawkins (a member of the Board) in securing the Challenge Shield donated by the Royal Agricultural and Horticultural Society for the champion crop of the year. Most of the districts throughout the State carried on their competitions with commendable results. I take it that this is significant of the educational value in which members view this phase of Bureau work, and I am pleased to know that these and other districts are renewing their Competitions during the present season. I hardly know of any better means of ascertaining the best cultural methods for a district than these Competitions, and I feel that we should have a few thousand entries from year to year instead of a few hundred. Through the instructional staff, the Department of Agriculture is anxious to assist you not only in the matter of Crop Competitions, but in any way it is possible for them to do so. As Bureau members I wish to impress upon you that you have certain rights and privileges, and the departmental officers expect you to exercise them in order that they may carry out their duties on the one hand and further to take some part in increasing the production of your farms, as well as in regaining the general prosperity of the State.

TUESDAY, SEPTEMBER 13th.

Morning Session.

Mr. Alan H. Robin, B.V.Sc. (Government Veterinary Officer, Stock and Brands Department) read a paper on "Mammitis, Milk Fever, and Contagious Abortion in Cattle." The paper is published as a separate article in the *Journal.*

RESOLUTION.

Following a very interesting discussion in which Mr. Robin replied to many questions Congress unanimously resolved:—"That this Congress realising the importance of the dairying industry and the serious losses incurred through the ravages of mammitis requests the Stock and Brands Department to conduct field experiments to ascertain the value of the various vaccine treatments at present on the market in order to assist dairymen in their efforts to overcome this scourge."

Mr. A. J. Cooke (Vice-Chairman, Advisory Board of Agriculture) read a paper on "The Paterson Scheme," which is published elsewhere in this issue.

At a separate session an address was given by Dr. Davidson (Waite Research Institute) on "Some Economic Insect Problems of Orchard Fruits in South Australia," and papers were read by Mr. Max J. Vickers (Lenswood) on "A few Impressions of Future Trade Prospects in the East for our Fruit and Vegetables," and Mr. R. Nosworthy (Balhannah) on "Bees—Life and Culture." The former paper is published in this issue as a separate article, and Mr. Nosworthy's paper will appear in a subsequent issue.

RESOLUTION.

At the instance of Mr. C. Robertson (McLaren Flat), seconded by Mr. H. B. Richardson (Penola), it was decided that this Congress strongly stresses the importance of compiling all records at the Blackwood Experimental Orchard and put them into safe keeping.

Afternoon Session.

Mr. A. G. Barrett (Barrett Bros. Pty. Ltd., maltsters) read a paper on "Malting Barley on the Farm and in the Malt House," which is published as a separate article.

A paper on "Wheat Varieties in South Australia," prepared by Mr. R. C. Scott (Supervisor of Experimental Work) was read by Mr. W. J. Spafford (Deputy Director of Agriculture). Mr. A. Lyell McEwin also read a paper on "Methods of Improving Draught Stock Breeding." Both papers appear elsewhere in this issue.

Evening Session.

At the evening session Prof. A. J. Perkins (Director of Agriculture) read a paper on "Some Points in the Handling of a Fat Lamb Flock on a Mallee Farm," which will be printed as a separate article.

FREE PARLIAMENT.

Wednesday Morning.—September 14th.

The following resolutions were carried :—

Redhill Branch—"That the Commissioner of Railways consider reducing the railway freights with a view to increasing business."

Yurgo Branch—"That rail freight on super. be reduced 50 per cent., also pointing out that if applicant to the Farm Relief Board be allowed sufficient super. per acre, the return freight in wheat will by far exceed the loss on reduced super. freights."

Pygery Branch—"That the Railways Commissioner give special reductions in freight in cases of stud stock."

Tatiara Branch—"That the import duty (or tariff) on all materials used in the manufacture of superphosphates be removed."

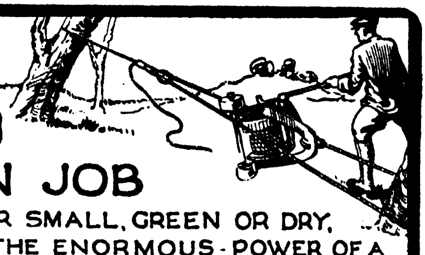
Laura Bay Branch—"That the restriction on the importation from America of Farm Journals be removed."

Port Elliot Branch.—"That Parliament be requested to amend the Motor Vehicles Act to allow more freedom to Primary Producers."

Blackwood Branch—"That districts that are not in touch with railways should not be "controlled roads."

Warramboo Branch—"That the Farmers' Relief Extension Act of 1931 be altered and a clause be inserted therein whereby the Relief Board shall have power to allow the farmer the necessary service fees for the purpose of breeding up stock to replace old and worn out ones."

Warramboo Branch—"That the Farmers' Relief Extension Act of 1931 be altered and a clause inserted therein whereby the Board shall have power to grant the farmer a percentage of the proceeds of his crop to meet necessary expenses which are not at present provided for under the Relief Act."



GRUBBING
IS A ONE MAN JOB
FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A
MONKEY GRUBBER
EASILY ACCOMPLISHES THE TASK
Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.
Each part designed for simplicity, easy handling, and long trouble-free service.
A TIME SAVER AND PROFIT MAKER
ADELAIDE STOCKISTS—Australasian Implement Co., Colton, Palmer & Preston, Harris Scarfe Ltd., McPhersons Pty. Ltd., South Australian Farmers' Union.
TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

Miltalie Branch.—"As superphosphate is so very essential for the production of wheat and other fodders, we consider that a reduction in price is long overdue. Manufacturers have demanded spot cash for the last two seasons which should enable them to sell at a lower price."

Belvidere Branch—"That in view of the activities of the Society for the Prevention of Cruelty to Dumb Animals a committee be formed in each district to safeguard our interests in respect to rabbits, horses, and stock generally, and suggest that in the event of action being taken in any case, evidence by two experienced farmers or teamsters be accepted."

Bundaleer Springs Branch.—"That approved veterinary surgeons be subsidised in various districts of the State."

Wallala Branch—"That the Government allow the State Bank to assist farmers to purchase approved stallions."

Clanfield Branch—"That Congress is stongly of the opinion that all lubricating oils and greases offered for sale should have the container branded with the grade and guarantee of purity of contents."

Wallala Branch—"That the Government be asked to renew the subsidy for District Crop Competitions."

Yeelanna Branch—"That some future recognition be given to competitors receiving 2nd, 3rd, and 4th positions in the State Championship of the Wheat Crop Competition."

Laura Bay Branch—"That the Crown Lands Department be approached to supply poison, and (or) make provision to destroy rabbits on Crown Lands in farming areas, District Councils or Vermin Boards to supervise same."

Maltee Branch—"That the Advisory Board of Agriculture endeavor to force all delegates to attend at least two-thirds of the Congress meetings, otherwise the delegates forfeit their fare to and from Adelaide."

Tatiara Branch—"That the old and new rule of members be abolished, as it penalises the new members, and that is the only way in which the Bureau will prosper."

Langhorne's Creek Branch—"That the Congress Agenda be sent out to Branches six weeks before Congress."

Murray Bridge Branch—"That the Government take from the Motor Transport Board all control of Primary Produce."

RESOLUTIONS LOST.

Black Springs Branch—"That this meeting of delegates urge various Governments to pay another bounty of 6d. per bushel on wheat for this coming harvest."

Greenock Branch—"That a registration fee of £1 1s. be charged-for each stallion to provide the nucleus of a fund for subsiding suitable stallions on lines similar to the subsidised dairy bulls scheme."

Clanfield Branch—"That in the interests of our primary producers Congress recommends that the Department of Agriculture publish a text book on our rural primary industries."

Pinnaroo Line Conference—"That in the opinion of this Congress the new rule *re* membership should be rescinded and that a *Journal* levy on all members be introduced and paid by each Bureau member entitling him to a copy of the *Journal.*"

Evening Session.

A paper on "The Dairying Industry" was read by Mr. H. B. Barlow (Chief Dairy Instructor) and was fully discussed by delegates. This paper will be treated as a separate article in the *Journal.*

Mr. C. F. Anderson, (Government Poultry Expert) gave an address illustrated with lantern slides, "Recent Developments in the Poultry Industry."

At the invitation of Mr. A. G. Barrett delegates visited the Lion Maltings on Wednesday afternoon, on Thursday morning they visited the Waite Research Institute, and on Friday the Government Produce Depot at Port Adelaide.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

The Eastern Division of the Murray Lands, represented by the Loxton, Paruna, Taplan, Meribah, Caliph, and Alawoona Branches of the Agricultural Bureau, met in Conference at Paruna on September 27th. Mr. A. C. Webb (Chairman of the local Branch of the Bureau) presided, and Messrs. S. Shepherd (Member of the Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert), R. L. Griffiths and P. H. Suter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary, Agricultural Bureau) attended on behalf of the Department.

The opening address was delivered by Mr. Shepherd, and the following papers were read and discussed:—"Conservation of Fodder," Mr. H. C. Webb (Paruna); "Costs of Production," Mr. E. D. Symon (Loxton); "Value of Experimental Stations of South Australia," Mr. H. Pengilly (Alawoona); "Co-operation and the Agricultural Bureau," Mr. P. Hodge (Taplan); "Some Observations on Bureau Meetings," Mr. A. McKenzie. An excellent agenda provided good discussions, and Departmental officers replied to numerous questions. Conference carried the following resolutions:—

"That the 1933 Conference be held at Taplan."

"That the old and new rule of members be abolished, because it penalises new members."

"That the Government be asked to renew the subsidy for Crop Competitions."

"That this Conference protests against undue interference by inexperienced officers of the S.P.C.A."

The evening session was occupied with an address, "The Poultry Industry," by Mr. C. F. Anderson (Government Poultry Expert).

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. SANDFORD & Co., LIMITED, reported on October 3rd, 1932.

BUTTER.—Production throughout the State continued to increase throughout September, and it is many years since such propitious weather for dairying has been experienced in this State. The result was that increasing supplies of cream came forward to the various factories and heavy shipments of butter went forward each week to London. The local trade was well maintained, but owing to London values having eased, rates moved back in sympathy here, and at date are:—Choicest creamery fresh butter in bulk, 1s. 2¼d.; prints and delivery extra (these prices are subject to the stabilisation levies); well conditioned store and collectors, 8d. to 9d. per lb. at store door, less usual selling charges.

EGGS.—Record quantities of eggs were handled throughout the month, but the peak of production seems now to have been reached, although warmer weather would no doubt stimulate production. Packing for export is still proceeding apace and will continue until the end of November. Unfortunately, a large proportion of the eggs arriving from country centres will not pass the graders for export, and this surplus has to be disposed of for pulping and other purposes. Ordinary country eggs, hen or duck, 5d. per dozen; selected, tested, and infertile higher.

CHEESE.—The South-Eastern factories are manufacturing very heavy quantities of this commodity, and although local and Western Australian traders purchased up to the average quantities, there was a considerable surplus for export which was shipped to London from week to week. Rates continued steady. New makes, large to loaf, 7¾d. to 8¼d.; semi-matured and matured, 10d. to 11d. per lb.

BACON.—The turnover in bacon continued at a high level throughout September, the advent of the Royal Show helping in this direction. Some interstate trade was also negotiated, Queensland and New South Wales purchasing some quantities and Tasmania also bought occasionally. Values have improved in some of the lines, and the demand has been keeping up well. Best local sides, 8½d. to 9d.; best local factory-cured middles, 8½d. to 9d.; large, 8d.; local rolls, 8½d. to 9d.; local hams (raw), 11½d. to 1s.; cooked, 1s. 2d. to 1s. 3d.; lard, prints 6d. per lb.

ALMONDS.—Only limited quantities of almonds were marketed throughout September as most of the growers have ere this sold the bulk of their supplies. Buyers therefore were unable to obtain all their requirements, and the various markets are being kept clear of stocks as they arrive. Brandis and softshells, 9½d. to 10½d.; hardshells, 6d. to 6½d.; kernels, 2s. 1d. to 2s. 2d. per lb.

HONEY.—No improvement in the demand for honey was recorded, and tinners and wholesalers are holding considerable stocks. Until an outlet is found overseas for this commodity the market is dull. Prime clear extracted, in liquid condition, 3¼d. to 3¾d.; second grade, 2d. to 2½d. per lb.

BEESWAX.—Selling steadily at quotations:—1s. to 1s. 1d. per lb.

LIVE POULTRY.—The sales of live poultry throughout the month were well attended by buyers, but the quantities submitted were not as great as in other months of the year. This, however, is usual, and with keen competition all lots met with ready quittance at satisfactory prices. We advise consigning. Crates loaned on application. Prime roosters, 3s. 8d. to 4s. 9d.; nice conditioned cockerels, 3s. 2d. to 3s. 7d.; fair conditioned cockerels, 2s. 9d. to 3s. 1d.; chickens, lower; heavy-weight hens, 3s. to 4s.; medium hens, 2s. 6d. to 2s. 11d.; light hens, 2s. to 2s. 5d.; couple of pens of weedy sorts, lower; geese, 3s. 6d. to 4s. 6d; prime young Muscovy drakes, 4s. to 5s.; Muscovy ducks, 1s. 9d. to 3s.; ordinary ducks, 1s. 8d. to 2s. 6d.; ducklings lower; turkeys, good to prime condition, 8d. to 9d. per lb. live weight; turkeys, fair condition, 6d. to 7d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 5d. to 6d. each.

POTATOES.—4s. 9d. per cwt.

ONIONS.—New season's, 42s. per cwt.

RAINFALL TABLE

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of, and to the end of September, 1932, also the average precipitation to the end of September, and the average annual rainfall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

REPORTS OF BUREAU MEETINGS.

WOMEN'S BRANCHES.

SESSIONS AT THE 43rd ANNUAL CONGRESS OF THE AGRICULTURAL BUREAU.

Members of the Women's Branches of the Agricultural Bureau opened their business session in Way Hall on Tuesday, September 13th. Mrs. J. Hammatt (Williamstown) was elected Chairman, and Mrs. Clifford (Penola) Hon. Secretary of the Congress.

In extending a welcome to the delegates, Mr. F. Coleman (Member of the Advisory Board) said it was being recognised that women were becoming a powerful factor in the primary producing spheres, and all that the Bureau stood for. The women outback were having a particularly hard time. It was pleasing to know that women were taking over the management of dairy herds, and it was safe to predict that their activities would assist materially in the progress and development of the country.

The following papers were read:—

POULTRY RAISING.

[By Miss L. A. McKay, Penola.]

In dealing with this subject, I write of facts brought about by several years of practical experience, by which I have succeeded in making poultry raising a profitable investment, as well as an interesting hobby.

The majority of women residing in country districts usually desire some out-of-doors hobby which may assist to vary the routine of domestic labors, and in taking up poultry raising it is possible to create a hobby of absorbing interest, as well as of profit.

Several characteristics are necessary to ensure success, the principal are perhaps "Interest," whilst "Regularity" is also an important factor. In practically all homesteads on the land, there are to be found several acres adjacent to the house that are not utilised for any particular farm activity. These oddments can be turned to account by using them as a free range for poultry.

Fowls confined require a good deal of attention, and although this idea is supported by many experts, yet it is not desirable where the attendant may have many domestic duties to attend to. Most country homes have a bevy of fowls of the ordinary "barnyard" variety. They supply eggs at odd times during the year.

In farming areas it is the custom to set aside so much grain for fowls' feed during the year, and little or no account is kept as to whether their presence is a profit or a loss to the place.

In starting a flock of fowls, a line of pure-bred stock is most necessary. The popular breeds in country districts seem to be the White Leghorn, the Black Minorca, and the Black Orpington. I have found that the values of various tested breeds vary according to climatic conditions. In the cold, damp areas, the Minorca seems to do better than either the White Leghorn or the Black Orpington.

Locally, I have found that Black Orpingtons are very susceptible to roup and ''scaly legs,'' thus necessitating much treatment. With the foundation of the flock solidly built upon good blood lines, one can experiment with cross breeding to produce a utility type.

CROSS BREEDING.

In the poultry world, at frequent intervals, new breeds are produced by expert breeders, the outcome of cross breeding. Therefore, how much more interesting for one to breed a type of fowl most suitable for their own particular line of business? I have experimented with three classes of cross breeding, and can safely recommend them as being a type most desirable as utility birds.

A pen of White Leghorn hens mated with a Barred Rock male bird produces birds of a very good type. The hens are excellent layers, and although not heavy brooders, yet make good mothers, and have sufficient of the ''heaviness'' of the Barred Rock to be quite a good type of bird for table purposes. Another class, bred from Black Orpington hens mated with an Indian Game bird, produces a fine type of utility bird. Of wonderfully robust constitution, they are an excellent class of bird for the cold, damp areas. Whilst inheriting the shape of the ''Game,'' with the accompanying characteristic of self defence against enemies, they possess the laying qualities of the Orpington, and although somewhat inclined to brood heavily, are easily dissuaded against so doing when removed from their nests. In appearance they are beautiful birds, possessing a lustrous, close plumage of a blue-black hue.

The hens are excellent mothers, being always on the defensive against the attacks of hawks and other pests. As table birds they are unsurpassed, and thus ensure a good return when sold. Cockerels of this cross attain the weight of 7lbs. and 8lbs. by the time they reach the marketing age, which is usually from five to six months, and are sure of gaining the highest price.

Yet another excellent utility type can be bred from Barred Rock hens mated with the Indian Game. In all characteristics they are similar to the Black Orpington-Game cross, with the exception of the color, which actually enhances the appearance of the bird, as the ''speckled'' or ''barred'' plumage is of very deep markings.

FEEDING.

I use a method which will probably be condemned by many as being unorthodox. Nevertheless, I have proved it profitable. Regularity is most essential. At whatever hour is most convenient in the morning to feed them, be sure that each day sees the meal being distributed at the same hour. I feed my fowls once a day, at about 8.30 each morning. To each fowl I allow approximately one handful of grain (usually wheat). A special shed, well away from the house, is used as a granary, and from there I convey the grain and scatter it over as large an area of grass land as possible. In scratching for it, the fowls not only have healthful exercise, but they find much insect life, and thus are encouraged to roam further afield. By feeding only once a day, they are not encouraged to linger around awaiting for the evening meal, as is customary with all fowls who are fed towards evening.

Several small drinking vessels, set in shady places at various points, are more satisfactory than one large one. Kerosene or petrol tins, cut lengthwise, answer the purpose. They should be scoured daily with a brush, to ensure the removal of any slimy substance which frequently adheres to the sides, if the cleansing operation is neglected. An occasional ''swilling'' with caustic soda and warm water is also advisable, as an additional precaution in cleansing. A plentiful supply of clean water is most essential, as fowls drink copiously at almost any time of the year. In the hotter weather frequent replenishing of the water must be strictly attended to.

During summer, when green feed is not always plentiful, I have found it advisable to add Epsom salts to the drinking water, usually at the rate of two packets to 2galls. of water. This acts as a tonic and materially assists the poultry during the moult. During winter and spring I frequently add ''Merval'' to the drinking water.

AILMENTS AND DISEASES.

With the coming of the earlier rains and cold, damp weather there is always the possibility of colds breaking out amongst the fowls. A neglected cold can terminate in roup, and as a safeguard, a few drops of kerosene dropped into each drinking vessel during the later autumn days usually acts as a preventive. If, however, an outbreak of colds should occur, isolate immediately the affected bird, and put in a warm, dry place. Cleanse the nostrils, and in each drop a little kerosene. Administer 5 grains aspirin (or aspro) in either a whole tablet form or by crushing to a powder and mixing with dripping. Repeat twice daily, and in a short time the bird should be cured. These simple remedies can often prevent a serious outbreak of sickness in the flock.

Another malady common to most fowls is that of becoming ''crop bound.'' That, too, can easily be prevented if taken in its early stages. Half a teaspoon of bicarbonate of soda, dissolved in warm water, and administered to the bird, followed immediately by a copious dose of olive oil (from two to six teaspoonfuls, as the case may require), usually removes the cause of the trouble.

''Scaly leg'' is another complaint common to the heavier breeds of fowls in damp climates. A mixture of equal parts of kerosene and olive oil applied to the legs and toes is very effective.

It is not desirable to be catching fowls too frequently for the purpose of treatment. I have found that by having a jar of this mixture kept close at hand to the house wherein I keep broody hens, I can apply it to any of the hens who require it. As the heavy breeds of fowls usually brood fairly frequently, they can be treated just as often as is necessary and yet not unduly disturbed.

BROODINESS.

Many people complain of having trouble with hens brooding for long periods. I have found little or no trouble in treating them for this. Have a small, well lighted shed in which to put them at the first sign of ''broodiness.'' If two ''broodies'' are not available at the same time put another fowl in. Feed and water in the house, and in from five to seven days they will be quite off the brood.

PERCHES AND HOUSING.

A large, roomy shed should be at the disposal of fowls for the purpose of roosting. If facing the east, they can get the benefit of the morning sun in the winter months and avoid the colder winds. Perches placed on sloping beams, extending from the extreme back wall to the foreground of the shed, are very satisfactory.

Limestone gravel, well set, is a clean and healthful ''flooring.'' It can be easily cleaned, and the limestone is of assistance in keeping down any vermin.

If the shed is set in a substantial wire-netted yard, the gate can be closed at night as a safeguard against foxes or other marauders. Frequent applications of lime wash in and around the walls and perches should prevent any danger of vermin.

Although obviously very unorthodox in my treatment of poultry, I have found that it is possible to have healthy, contented birds without bestowing more than half an hour upon them daily, excepting, of course, the occasional cleaning up days of the houses.

In conclusion, I would suggest to anyone who has a satisfactory flock of fowls to never breed from any but the pure bred birds, and to cross only from two pure bred breeds. Avoid most religiously the setting of eggs frequently offered by a generous friend. Their birds may appear all right, but in all probability their progenitors were purely mongrel. Keep an account of all eggs gathered and sold, and all birds sold; also keep a strict account of all food costs. It is the only way of obtaining accurate evidence, at the end of the year, whether the flock has paid or not.

USEFUL HOUSEHOLD HINTS.

[By Mrs. M. J. White, Parrakie.]

Preserving Cut Flowers.—Certain flowers, like the flag, lily, pansy, and others slough away when put into water. Cut off the end of the stems frequently. Wild flowers develop and fall quicker than garden flowers. Flowers plucked in the bud last longest; always place in water as soon as possible after being picked. When received by post in a wilted condition an immediate plunge into hot water to which has been added a little sal volatile will accomplish wonders. Flowers can be made to last the whole evening if the ends are sealed with a piece of wax.

To Prevent Rust.—Stoves, grates, or any iron may be left for months without further care by making a paste of fresh lime and water; smear thickly. When required again, brush off with a stiff brush.

To Repair Rubber Hose.—Cut out the bad part; get a piece of iron pipe three or four inches long the size of the inside of the hose, twist the hose over it until the ends meet, bind with waxed string or thin wire and it will last for years.

To Clean Tennis Balls.—Dissolve a cake of pipeclay or a quarter pound whiting in as much boiling water as it will absorb. Stir well with an ordinary tallow candle until it is about half melted; let cool. Brush the tennis balls with a stiff whisk in order to remove dirt. Take a little of the pipeclay mixture, mix with cold water to the consistency of cream, and apply to the ball with a brush or sponge.

Mice.—To keep mice away, place camphor in trunks or drawers and it will prevent mice doing any damage. Pennyroyal or mint placed on shelves will cause mice to forsake the house.

Tough Meat.—Add a tablespoonful of vinegar to the water in which tough meats or fowls are boiled; it will make them as tender as a chicken.

To Clean Casks.—Put a few pounds of unslaked lime in the barrel, add water, and cover. In about half an hour add more water and roll well. Then rinse with clean water. If not wanted, put 1lb. lime to a bucket of water and put in cellar.

Prickly Heat.—A bath of common salt or carbonate of soda is good. If very severe, a spoonful of sulphuric acid in a full bucket of water, used as a sponge bath, will give almost instant relief.

Lime Water.—1oz. fresh lime in 1 pint of water, strain and bottle.

Carron Oil.—Used for burns. To 4ozs. lime water add drop by drop 1oz. of olive oil. Stir until it forms an emulsion. Keep in a well-corked bottle and shake before using.

Clothes, Size of.—A size in a coat is an inch, in underwear 2ins., in a sock 1in., collar ½in., shirt ½in., shoes ⅛in., trousers 1in., gloves ¼in., and hats ⅛in.

Cane Seats.—To clean and tighten, sponge with lemon juice and salt, rinse with warm water, turn upside down, and leave in the sun to dry.

Cakes.—When baking, place a basin of water in the oven and the cakes will not burn. Always flour fruit before adding to cakes and puddings. Open and shut the oven door carefully when cooking sponge cakes, because a rush of cold air will make the cake drop in the centre.

Paint on Windows can be easily removed by making a strong solution of bicarbonate of soda. Wash the glass and in half an hour rub thoroughly with a dry cloth. Turpentine is also good.

SOCKS AND STOCKINGS (DEMONSTRATED).

[By Mrs. E. L. Orchard, Belalie.]

Stockings, like other clothes, possibly resulted from the desire to protect the legs from cold weather, though the very latest in stockings, according to a recent arrival from England, are made in finest of silk fish-net material, so there would not be much warmth or serviceability in them.

Stockings have been worn by civilised people for many years, but there are some in the summer time who prefer to go without the usual leg covering and wear sun-tan instead. Thirty years ago plain black cashmere for everyday wear and open work in white cotton or silk for parties, were the only stockings worn, and it is only during the last 15 or 20 years that they have become so very interesting, made in every shade to match every frock; heavy in winter, fine in summer, and sheerest for evening wear.

Many years ago all socks and stockings were made by hand, and it is only with the advent of machinery that it has been possible to make them of fine texture in silk and artificial silk. The hand-knitted ones are certainly very serviceable and quite fashionable for golf or a hike, but would it not be tragic for the present generation if we were suddenly deprived of the machine-made article?

It is not easy to repair at home fine stockings, though now that it is possible to have them mended by professionals at a small charge per inch it is not worth trying to do them at home, because unless one is an expert needlewoman the result is not satisfactory.

Ladders in silk or lisle stockings can be mended by turning the stocking inside out and machining with a very fine stitch, a little more than the length of the ladder, and when a heel has to be darned, if a tiny tuck is taken under the foot where it will not be uncomfortable in wearing, the darned heel will not show. Sometimes the suspender causes a tear or hole in the top of the stocking; if that is stitched all around and across by machine, it makes a strong mend and prevents a ladder. When a stocking shrinks in washing, the hem at the top can be cut open, hemmed again with a small turning, stretching well as it is stitched with the machine, and so give extra length.

Lisle and mercerised cotton stockings, after being darned a few times, can best be repaired by refooting. First cut the hem to make the leg longer, then cut out the worn part of the foot. From a leg that is sound cut two pieces of this shape—D—and proceed to refoot the stocking in this way. To form the heel, sew across the cut end of the stocking for about 1in. at the seam, then put in the D-shaped piece and the stocking will give another few weeks of wear. Men's cashmere socks can be made sizes smaller to fit a child in this way and are quite comfortable to wear.

Woollen hand-knitted socks can be refooted by cutting off above the most darned part, unravel a few rows, pick up stitches on needles on which the socks were knitted, and continue knitting as if making for the first time. A heel that has been worn before the toe can be replaced after the same manner, only it is the heel stitches that are unravelled, picked up and reknitted, grafting to finish, so that it will not be bulky in wear.

When stockings and socks have finished the work they were originally intended for, there are many uses to which they can be put. From black cashmere a neat pair of child's bathers, a mask for fancy dress occasions, golliwogs, caps, and dusters can be made. The bathers exhibited were made from one pair of S.W. stockings, and if O.S. are used, three legs will make a suit large enough for a child 8 to 10 years of age. The mask saves blackening the face if one wants to represent a Christy Minstrel or an aborigine, but, of course, is too hot for summer wear. One stocking makes a mask. Cut the leg for about 8in. and put in a V-shaped piece taken from further down the leg; call that the back, cut the mouth and eyes in the front, and oversew edges to keep the shape.

The golliwog is made from one cashmere stocking stuffed with clippings from a hooked rug; a cotton reel stiffens the neck, an old piece of astrakhan for hair, and a bright scrap of cotton material for the bow.

Boys' caps can be made in various shapes from two legs of stockings. If all the leg is without darns they only need to be cut down the back seam, joined together, and stitched like a "Johnny" cap or gathered at one end and a tassel attached or the end brought over to the side and fastened with a button. The polisher is made from all the darned feet and cut-off parts in the making of the other articles.

From a light-colored pair of fine woollen stockings, S.W. size, a small singlet or petticoat is made, and of course the larger the stockings the larger would be the singlet. First open the hem and then cut down the seam at back, lay it flat, and place second stocking—after being cut in the same way—on it. Use the top of the stockings for the bottom of the singlet, shape the neck and shoulders, armholes are left, and cut pieces from further down the leg to go from hem to underarms, to make the singlet wider. Tidy the seams on the inside for comfort and finish all edges with crocheted wool. Another use for woollen stockings—particularly those worn for golf—is to make a hot waterbag cover. Cut open in the same way as for the singlet, shape ½in. longer, and wider than the bag, and stitch.

White lisle or stockings of similar material can be used to patch summer-weight singlets and underpants. By opening down the back seam quite a large piece of elastic material is provided. Toecaps to wear under sheen evening stockings can be cut from sound parts of lisle hose.

There are many uses for silk stockings. They make comfortable sleeves to wear under a hug-me-tight or any woollen bedjacket if a person has sensitive skin. Cut off the feet and hem the ends tidily, and they can be pulled up over the arms and fastened with safety-pins to the shoulders of the nighty. Cut in ¾in. strips, or wider if they are very thin, and crochet into an oblong, square, or round; line with something strong to keep it firm, and you have a mat for the floor. A pretty bedroom cushion can be made in the same way. One stocking cuts from five to eight yards long, and a woollen stocking cut in a long strip would help in the making of a hooked rug. The tops opened and stitched together make a good duster, and feet and odd pieces all stuffed into one leg that is past wearing, then covered with cretonne, makes a good "sandbag" to put by doors in dusty weather.

Also, an unravelled silk stocking makes good padding for pin cushions. Old woollen socks and stockings cut down the back of the leg and opened out flat make good packing for winter rugs for the sleepout beds, and you all have possibly helped to make them for the Outback Relief. A dish mop and a floor mop can be easily made from pieces of lisle or woollen legs, the most important point being to secure the pieces very firmly to the handle.

In conclusion, I would like to emphasise the fact that it pays to buy good quality articles. Poor quality might stand one mending day, but the good ones in every variety will stand up to the wear and be of some use afterwards.

CHILDREN.

[By Miss R. Haines, Nelshaby.]

Children of to-day are the leaders of the generation to come, therefore it is the duty of parents, guardians, and teachers to study the dispositions and ambitions of the children, fitting them for the responsibility that one day will be theirs. Every child born into the world has a gift, which needs developing; it is our duty to endeavor to find for what particular calling a child is gifted. No matter how young, a child at its play often shows some sign of intelligence, which can easily be recognised and should be developed. The early years of a child's life should be filled with loving care, laughter, and sunshine. As Byron says, "A lovely being, scarcely formed or moulded, A rose with all its sweetest leaves yet folded." From infancy onwards a child needs careful attention, or otherwise bad habits may form, which are easier to prevent than cure.

When a child reaches the school-going age, and is sent to school, it is the first break in its life. The first years are spent in the home, mainly with its mother; when sent to school everything is changed. The atmosphere of the infant school is as the sunshine is to young plants, stimulating growth and enabling the life to unfold in all its beauty. To have power to create the right atmosphere the teacher must adjust her own inner life, so that a spirit of peace may prevail.

The children living in a town have a great advantage over their country cousins, by having kindergarten classes to which the children can attend. It gives them an idea as to what the school days ahead will be like. Children should be encouraged to play. "All work and no play makes Jack a dull boy." Some children are very hard to manage, needing a firm hand to bring out the best in them, whilst others need loving care and gentle handling. The main responsibility starts when a child leaves the primary school. Some are sent on for a higher education, others are kept at home. This is the time when the ambitions of the child should be studied.

Parents should if necessary sacrifice some of the pleasures of life to help their child achieve his or her life's ambition. If a child misses this opportunity in life, in some cases his life is ruined.

Ah! what would the world be to us
If the children were no more?
We should dread the desert behind us
More than the dark before.

THE USE OF KEROSENE IN THE HOME.

[By Mrs. E. P. Wall, Eurelia.]

Many housewives do not fully appreciate the uses of kerosene. Here are some ways kerosene can help the housewife. A teaspoonful or so in the copper will help whiten the clothes on washing-day. If the clothesline becomes rusted through damp weather, rub it over with a kerosene rag.

Add a cup of kerosene to the bucket of soap just before removing it from the fire; this helps to loosen the dirt in the clothes on washing-day. A dash of kerosene in the water used for washing the kitchen floor helps to brighten and disinfect the linoleum, also a nice gloss can be noticed when the floor is dry. A little kerosene on the duster will help pick up the dust more easily. If the supply of machine oil is exhausted, take a feather dipped in kerosene and just touch around the different parts; it will help to take the stiffness out and clear away any dirty oil.

When washing the head add a teaspoonful to the last rinsing water. This makes the hair bright, cleans the scalp of dandruff, and for school children destroys vermin in the hair. Moisten the knife polish with kerosene instead of water; it removes stains more easily.

A tablespoonful in a dish of warm water is an effective mixture for removing dirt and stains from the windscreen of motor cars. I have also washed the enamel of the car over with this mixture. The enamel seems to freshen up to its original color.

A small quantity of kerosene poured in an underground tank destroys mosquitoes and other insects without affecting the taste of the water.

For tar on clothes take a clean cloth, and with a pad of clean material underneath the tar, rub the spot with a little kerosene. Rub until the tar disappears.

BREAD MAKING ON THE FARM.

[By Mrs. F. Chilman, Warramboo.]

The baking of home-made bread is an art that seems to be dying out. Excepting in very isolated places, bakers' bread is available at least twice weekly, and farmers' wives are more and more giving up the habit of home baking and are buying their bread ready made. But, somehow, home-made bread has always been an institution in the country, and such an essential part of farm life that it seems all wrong for the farm home to be supplied by the baker with bread, especially in places where we have an abundance of wood for baking for only the trouble of picking it up.

As bread is a principal item of diet in every home, the making of it is a continual task, and for that reason the first essential in choosing a method from among the dozens there are is simplicity. Most of the recipes in use are too complicated and take up too much time and labor for the busy housewife, and this is the chief reason why many people give up doing it. Doubtless these elaborate systems make a beautiful loaf, but very satisfactory results can be obtained quite simply and with very little labor. As bread baking must be at least a twice weekly task, it should be the aim of anyone who undertakes the job to do it with as little labor and wear and tear as possible.

Acid bread is made very simply, but is not to be recommended for its continual use; it is not wholesome. It does not comply with the Pure Foods Act, and a baker is liable to a heavy fine for using acid in bread. Lemon yeast is a similar though better method and is fairly satisfactory, but for pure quality and wholesomeness nothing can equal bread made with hop yeast. Hops give the bread a fine flavor and texture that nothing else can.

YEAST RECIPES.

There are various ways of making hop yeast, but it is not at all necessary for it to be boiled; the hops only need to be scalded and soaked. The best plan is to keep a jug, or similar receptacle, for the purpose, and in this place a good pinch of hops, and add ½ pint or slightly more of boiling water. This can be set aside for any number of days, and all that needs to be done when wanted is to strain and add 3 tablespoonfuls each of flour and sugar, pour into a seasoned bottle, and in hot weather the yeast will be sufficiently worked in three or four hours to set the bread with; a longer time, say eight or ten hours, is necessary in cold weather.

The yeast need not be corked—only covered to keep out dust and flies. Refill the hop jug ready for the next batch. Potato water is always valuable for bread making, and should never be thrown away. Some needs to be added with the yeast when mixing the dough. In cold weather it is an improvement to put some in the yeast, but in summer this has a tendency to over-rise. Potato water that has been stored in the yeast bottle for a day or two has a wonderful effect if added to the bread when mixing, and if potatoes are boiled on other than baking days the water should still be saved.

The setting of a sponge some hours before mixing is considered a very important step by some bread makers, but in my opinion is only so much useless work and waste of time. Properly worked yeast, with potato water, can always be relied on to raise the bread within a reasonable time.

Correct mixing of the dough is a matter that needs some care, for a good deal of success depends on having it the right consistency, and very thoroughly kneaded, but with a little practice this is not at all difficult. The patent bread-mixers which are on the market at prices ranging from 25s. to 35s., according to size, can be confidently recommended as a complete success. One great advantage with them is that the men folk of the home will very willingly mix the bread by turning a handle, whereas the average man heartily dislikes putting his hands in the dough under any circumstances.

If making bread for show purposes, or for any special occasion, the addition of alum or cream of tartar makes it white and fine, but is not a good practice for continual use.

FAULTS AND FAILURES.

As a summary, we will take the principal faults or reasons for failure in breadmaking. When the bread is a dark color the cause may be inferior flour, or too much hops in the yeast. When it is streaky, or has hard dry lumps, it has not been sufficiently kneaded. Heavy bread is usually a cold weather complaint, and might be caused by the dough becoming chilled or not being left long enough to rise, or the yeast might not have been active enough. Warming the flour in the oven before mixing helps considerably in extremely cold weather. If the loaves are put in the oven before they are ready, they are apt to be holey and coarse; if the dough has been mixed too slack and wet, the result is much the same. Doughy bread, and bread with too much crust, are both faults that can be easily corrected by a proper manipulation of the oven; but the greatest calamity of all is sour bread. This usually occurs in very hot or thundery weather. Sometimes the fault is in the yeast, and a slight sourness can be checked by putting a pinch of baking soda in the bottle; but usually the only thing to do is to scrub the bottle out and start again; but more often bread is sour through having been left too long before baking and being over-risen.

Practice, foresight, and common sense are the greatest needs in the making of good bread, but the ability to make a good wholesome loaf is an achievement that is well worth the effort of striving for.

HINTS ON DAIRYING.

[By Miss E. Paddick, Kangarilla.]

In buying a cow there are three points to be observed, viz., large outstanding eyes, a bushy tail, and a square udder. A heifer should be about one year and eight months old before coming into milk. Kindness and gentleness go a long way in treating a cow, either old or young. Regular hours for milking are most important, and as much as possible the same person should milk the same cows. The cows should be well fed and sheltered from cold and wind.

In the preparation of dairy produce cleanliness is most essential. The separator should be washed and dried after every milking, and buckets, pans, &c., should be kept expressly for that use. Cream should be churned every other day; good butter cannot be made from stale cream. Butter should be handled as little as possible, especially in summer. One cannot be too particular with the handling of cream and butter.

FIRST AID.

[By Miss A. M. Laurie, Nelshaby.]

How often at the time of an accident do we hear people say, "If only the doctor were here," or "if I knew what to do?" while they should be saying, "Will somebody call the doctor, please, while I attend to the patient?"

No one rendering first aid should take upon himself or herself the duties and responsibilities of a doctor, but much good can often be done, and perhaps the patient saved from a great deal of suffering.

It must always be remembered that two or more injuries may result from one accident, and discretion must be used as to the sending for a doctor or taking the patient to him. Do not move the patient more than is absolutely necessary, and never remove clothing unless necessary. If clothing is being removed, always remove from the uninjured side first. Never try to remove a sock without cutting it, and if necessary with a coat, slit the seam of the sleeve of the injured side, and a shirt should be slit down the side and removed as a coat. Trousers should always be slit down the outer seam.

A first aid cabinet should be kept in every home, out of the way of children, but when accidents occur out of doors—especially in the country—materials often have to be improvised. This can be done, in the case of splint with a walking-stick, piece of wood, broom or brush handle, rifle, or better than nothing is a folded coat or paper. Bandages may be improvised by handkerchiefs, belts, or pieces of calico or linen. String or cord can sometimes be used.

Esmarck's triangular bandages are made by cutting a piece of material 40in. square, diagonally, into two pieces. This triangular bandage can be folded and used for almost any purpose, and one should be kept in every first aid box. Reef knots should always be used, as they do not slip and can easily be untied.

BROKEN BONES.

When a bone breaks a fracture is said to occur. This can be caused by direct or indirect violence and muscular action.

1. Direct violence, from a severe blow, a bullet, or crush of a wheel. The bone breaks where the force is applied.
2. Indirect violence, when the bone breaks at some distance from where the force is applied; for instance, falling on the hand and breaking the collarbone or radius, landing on the feet and breaking a bone in the leg.
3. Muscular action.—The kneecap and arm bone are occasionally broken by a violent contraction of the muscles attached to them.

Fractures are divided into simple, compound, and complicated. It is said to be:—

Simple, when the bone is broken, but with slight injuries to the surrounding parts.

Compound, when the bone is broken, and in addition the skin and tissues are torn, thus allowing disease germs to enter. This is often the case with a bullet wound.

Complicated, when the bone is broken, and in addition there is an injury to some internal organs, perhaps the spinal cord, lung, &c., or to some important blood vessel or nerve.

Also, a fracture may be compound or complicated, when the immediate result of the injury, originally simple, has been converted by careless movement of the patient.

Special varieties of fractures may be classified according to the injury to the bone itself; such as greenstick, in children, owing to the softer state of their bones; the bone may bend, and even crack, without breaking across. Impacted, when the bone breaks and the ends are driven one into the other.

General signs of fracture are pain at or near the fracture, motion of the part, crackling sensation of moving broken ends, alteration in shape, and often shortening. If the bone is close to the skin the fracture may be felt, and if compound it may be seen. Shortening is caused by the muscles contracting and so causing the bone ends to override. Bony grating may be felt or heard when the broken ends move one upon the other. This should only be sought by a doctor. Also some of these signs are absent in greenstick and impacted. Marks on the clothing or shin should be noted, as they may serve to locate the fracture.

TREATMENT OF FRACTURES.

Place the part in natural position, and keep it so with bandages and padded splints. If a leg be broken, after applying the splints tie the injured and the sound leg together at the ankle and knee and gently place the patient on a piece of board or shutter, but never remove patient until the whole leg is supported. More injury is often done after the accident than by the accident itself, especially in the case of the thigh.

If the lower jaw is broken, bandage the lower to the upper jaw with a handkerchief. For the collarbone, place pad in armpit, bandage elbow to side, sling the forearm. If the thigh is broken, apply a long splint from the armpit to outside of the heel, and a short one from the fork of the leg to the knee on the inside, and bandage. For the leg, apply splints inside and out and bandage. No attempt must be made to move a patient suffering from a fractured spine, except in a recumbent position, preferably on a stretcher. Should haemorrhage occur it must be attended to first.

DISLOCATIONS.

A dislocation is the displacement of one or more bones at a joint. The injury is accompanied by discoloration, swelling, and pain of a severe character at or near the joint. The injured part becomes deformed and fixed so that neither patient nor others can move it, and all parts below the joint become numb.

Support the limb in whatever position gives most comfort to the patient, and when taken inside, remove all clothing from around the injured part. Apply cold dressings—ice or very cold water. When necessary to give comfort, apply warmth—flannels or towels wrung out of hot water. The most common joints for dislocation to take place are the shoulder, fingers, or lower jaw.

SPRAINS.

When by a sudden twist the ligaments and parts around a joint are torn and stretched, the joint is said to be sprained. Going over on the ankle is a common example. The general signs of a sprain are the inability to use the joint, pain, swelling, and discoloration. If a sprain can be plunged into cold water immediately after the accident, it may prevent swelling, but hot or warm applications are necessary to remove it. Place the limb in a comfortable position, usually well raised, and apply hot fomentations with cotton wool and bandaging for some days. To bandage, begin at the instep and cross in front of the ankle, carrying it firmly around the ankle and tying. When the accident occurs the usual thing, of course, is just bandage it as firmly as possible. Wet the bandage if possible to make it tighter.

BRUISES.

Bruises may be caused from a blow, and this causes haemorrhage below the skin without breaking it. If a bruise can be treated at once, apply cold water, and keep the part at perfect rest; otherwise apply relays of hot fomentations, still keeping the part at rest. Later apply warmth and very gentle friction, with cotton wool, and bandage.

All of these injuries are the result of an accident of some type or another, and all require perfect rest. A day's absolute rest at the time of the accident is worth a month's afterward, therefore never neglect.

HINTS ON MAKING CAKE-BATTER.

[By MRS. H. ALTSCHWAGER, Millicent.]

There are three ways of adding eggs to cake-batter:—

1. The eggs can be broken into a bowl and stirred into the other ingredients without being previously beaten; that makes a rich cake, and one that will keep fresh better than when other methods are used, but the eggs will not help much in making the cake rise.

2. The eggs can be beaten, yolks and whites together, before they are added to the batter; a cake thus made will be lighter and less rich than that made after the first method, but it will not keep so well.

3. The yolks and whites can be beaten separately, the yolks added at the usual time, and the whites folded into the batter the last thing before it goes into the pan. The cake made in this way will be the lightest, but it will become dry sooner than either of the others.

There are also three ways of adding butter:—

1. The butter can be worked into the flour with the hand, until it is so thoroughly incorporated that its presence would be unsuspected by anyone. Many of the fine French cakes are made in that way. It gives an even although not the finest grain.

2. The butter can be melted and added to the batter the last thing, or just before the beaten whites of the eggs. That is the quickest way, but the grain of the cake may be uneven—a mixture of coarse and fine. In adopting this plan remember that the less you stir your batter before you add your butter and the more you stir it afterwards the tenderer your cake will be, for the gluten of the flour when much "worked" in the absence of shortening is likely to grow tough.

3. The butter can be creamed until it has the color and consistency of whipped cream; the sugar can be added, then the eggs next, and then the dry ingredients alternately with the milk or other wetting, until the batter is of the right thickness. That is the slowest and most difficult method, but it gives the finest grain.

Lastly, there are three ways of adding the fruit, the difficulty about which is that it has a tendency to sink in the batter.

1. The fruit can be well stirred; in fact, crushed into the creamed butter, before the sugar is added. By thus incorporating it with the butter its tendency to sink is reduced. This method produces a darker cake—but that is not always a disadvantage.

2. The fruit can be floured, and added the last thing to the batter. The flour increases the friction, and thus tends to prevent the fruit from sinking. But the novice must beware of using too much flour, or she will find uncooked patches in the cake.

3. The fruit can be heated, then added to the batter. The density of the fruit decreases as it swells, and also when the fruit is hot it coagulates a certain amount of batter that forms a coating round it. Thus in two ways friction is increased and the tendency of the fruit to sink is lessened.

If nuts or chocolate are used in making a cake, the amount of butter must be proportionally decreased, otherwise the cake will be so rich that it will fall. For example, if you use 1 cupful of butter to 3 of flour, which is the maximum, and wish to add a cupful of nutmeats or of grated chocolate, you should deduct a quarter of a cupful of butter for every cupful of nutmeats or chocolate that is added, for both ingredients are rich in fat. Nuts also require an additional amount of salt—a quarter of a teaspoonful for each cupful of nuts to develop the flavor. The added touch of salt makes all the difference between an excellent nut cake and a poor insipid one.

Cakes that contain a great deal of fruit and spices or nuts develop a fine flavor as they are kept; a nut cake is not at its best for a week after baking, and a cake with a lot of fruit and spices until it is a month old.

If you pack a cake fresh from the oven in brown sugar it will keep fresh for two months or even more, or ice the cake while hot and put it into the cake-box with a couple of green apples cut in halves.

On Tuesday morning Dr. Ethel Hillier spoke on "The Aims and Objects of the Home School." Mr. A. J. Quarrell gave a talk on "Gardens and Gardening."

On Tuesday afternoon Mrs. C. E. Dolling gave a travel talk, "New Zealand." A visit was made to the Farmers' Co-operative Union's establishment, at Mile End, where Mr. A. J. Cooke (Vice-Chairman of the Advisory Board of Agriculture) addressed and demonstrated to the visitors on the grading, packing, and marketing of eggs for local trade and export to London, supplemented by a demonstration on cream grading and butter making. Cars to convey delegates from the Way Hall and back to the city were generously provided by the management of the factory.

Under the guidance of Dr. Fenner and Miss Campbell, delegates on Wednesday morning visited the Unley Central School, and in the afternoon Miss E. Campbell, Dip. Dom. Econ., gave an address and demonstration, "Wool and its Uses," and Miss Armitage a demonstration of wool spinning.

The following resolution was carried:—That "First aid and how a child should act in the case of clothing catching on fire" be taught in public schools and also brought before all Branches of the Bureau.

For delegates' attendances see page 328, report of Annual Congress.

Reading as a Recreation for Women.—Miss Carter, B.A., read the following paper: Books are a big factor in a cultured life. Reading is educative in the highest degree, for books represent the accumulated wisdom of the ages, and we absorb ideas while quite unaware that the process is going on.

As there is no end to the making of books, so there is no end to the kinds of books offered to readers. Philosophy, History, Biography, scientific treatises; all attract a wide circle of readers, but the book meant when we consider reading as a recreation for women, is the novel. The novel as such is of fairly recent date. It was not until the 18th century that it first appeared with a social and domestic background and people in a familiar setting; though history, both of our own land and of Israel, as found in the Bible, is full of men and women, whose doings are of as great interest to us as any hero or heroine's created out of the imagination of an author, and I can recommend the Old Testament to anyone who is looking for interesting reading. It is a strange convention that has decreed that the most interesting book in the world and the one we hold in most veneration should be read on stated occasions only, and any further reading of it should be looked upon as a parade of virtue.

Everybody is interested in other people and it is this curiosity which gives us our interest in books. We read to see how the people in the story will meet the different situations in their careers. The author creates men and women who live and move in their own world and act as real people subject to the conditions and times in which they live. A character in a historical novel will be true to the period; a 17th century character will be different in many ways from a 20th century man but only in externals; the great fundamentals of loyalty, honor, and love do not change with the years.

We are all familiar with D. K. Broster's period novels, Baroness Orczy's "Scarlet Pimpernel" series which give an excellent idea of the Revolution Period, and many of Sir W. Scott's novels which reconstruct a by-gone age, and which bring to life many characters who would otherwise be mere names to us, but whatever the time in which they are to live, the author must make his men and women real to us—they must stand upon their own feet. If they do not they will be mere puppets, moving only as we see the strings pulled and they will fail to hold us.

No writer has given us more characters whom we think of, not as in the pages of a book, but as men and women who live, than has Dickens. Many readers complain that they cannot read the books. His canvas certainly is crowned, but with real living creatures, whose story, told with wonderful humour and great pathos and sympathy, will well

● FULL MOON.

repay the efforts put forth by the reader. This quality of being alive, of fidelity to life, is what marks a good book from the rest of the great numbers of books put forth each year. It is unreasonable to complain when we go to a library for our books that so many are poor in quality. Not every flower that grows is a champion, so we must not complain, when we choose books by the newness of the covers, if we are often disappointed. But time weeds them out, and the worth-while ones remain immortal. You are all familiar with the names of some of these immortals—Little Nell, Mr. Pickwick, Sam Weller, Tess of the D'Urbervilles, Jane Eyre, Dr. Jekyll and Mr. Hyde, Lorna Doone—to name only a few, but here perhaps more than anywhere familiarity breeds contempt, or at least indifference. We are all so familiar with their names that we do not trouble to become familiar with the people themselves to our own great loss, for here our prejudice deprives us of a great deal of enjoyment. The question of what we should read can be answered in many ways, according to our temperament, our aspirations; or perhaps according to our opportunities, for our choice is restricted—especially now that books are so expensive—to our ability to buy or to borrow from our friends or from the local library. For the majority, of course, the novel has a wide appeal. The proper study of mankind is man, and in the novel we see men and women living, loving, succeeding, or failing in their appointed tasks. In real life we seldom see the whole of the story—the separate incidents make no complete pattern—but in the novel the whole plot is before our eyes making a whole we can follow with added interest as the character unfolds and develops to the end. In every story there must be a plot, however slight, and here novels vary considerably, from the long story with its pages crowded with men and women—though many of these are not intricately woven—to many of the slight affairs turned out by the dozen. Many, while purporting to reveal life and hold a mirror up to Nature, do so in such a way as to give us a distorted picture of life. Even apart from the extreme cases, it is marvellous how little critical we are; behavior and incidents we would condemn most harshly in real life amuse us or are tolerated between the covers of a book, whereas we would be scandalised if they occurred in local life. The most intricate plots are not always the most successful stories. Take for example the mystery story. If well written we follow it with breathless interest. As the mystery deepens we pick up first one trail and then another, only to find ourselves more deeply intrigued till we reach the final solution. Then having solved it, we are finished with it. The jig-saw puzzle is complete and we search for something else to read. Nevertheless such books have their place—they beguile many a tedious hour. Edgar Wallace was a master hand at this kind of writing. He poured out his books at an amazing rate. His special power lay in his ability to create a new world in which we eagerly followed his heroes, forgetting while doing so our troubles and trials, and surely a man who can do this is entitled to his place in the stars. The books, however, which live, and to which we can turn again and again, are novels of character rather than of plot. The people are friends to whom we can go, always there whenever we come to visit them. There is something satisfying in turning the pages of a book one has enjoyed; comparable to visiting again those friends who are always the same. The very sight of the books is comforting. No one can fail to appreciate its value from a recreative standpoint. We all have a few such books that we can turn to. One big advantage of these friends is that they are always the same—whenever we find time to turn to them. A few minutes in which we can forget our troubles will send us back to them refreshed. Even the anticipation of a few minutes spell is of value in speeding up the work and making us forget the drudgery, so that work becomes a means to an end and not the end itself. I have found by experience that a book that appeals to one reader fails to interest the next. I often think that it is because they are led to expect too much, or perhaps from a desire natural to frail humanity—to appear superior, by criticising the other's choice. ("I can't understand what she can see in him—or it, &c.") There are, of course, a great number of capable writers of the present day, if we want our reading to be up-to-date; Warwick Deeping, Rose MacCaulay, Philip Gibbs, John Buchan, Clemence Dane, John Galsworthy, A. S. M. Hutchinson, &c., &c. I cannot conclude without some references to the why of books. E. V. Lucas, a very fine writer, is decidedly of the opinion that novels are for recreation, and must not set out to teach; but though the lesson may not be obvious, it is there. The writer tells us what he thinks of life. He sets out to expose pretence. How we all enjoy a laugh with Wodehouse, and how many of us realise that we are really laughing at smugness or inanity, or the over-serious golfer or the weakness of society at which he tilts for our edification. The author too sets out to praise integrity and endurance, to set out the nobility of manhood, and of generosity, and to reveal weaknesses, and if we read with understanding we cannot fail to see some lesson which is there for all to read. Our individual experience is limited in most cases, we have not the advantage of travel with its broadening influences, of meeting new people and of brushing shoulders with the giants of the day, but there are few of us who cannot meet these people in their books. Our acquaintanceship can be a big one—the writers who reveal themselves in their works, and their characters. The sayings and doings of a host of friends are there to enrich our lives. We can be transported at will to all lands far more cheaply and more comfortably than Cook's can do it, and as Shakespeare says, "Not one stomach shall be offended," a truly comforting assurance to all bad travellers. The genius of the author can create a new world in which we can live with, can even be, the hero or heroine, as we desire, we can forget ourselves and all the trials and pinpricks if we have any, and find we are carried from this time and place to other lands and ages; and then come back to realise there is a familiarity about our own home and people that endears them to us, for it is "familiarity that maketh a blessing dear." The worn rug, the familiar kettle singing on the hob, the dear ones dependent on us, mean more to each one than the manly hero or the beautiful heroine. If we are sensible we realise that though it is very nice to go on these jaunts, it is nicer still to come home, specially if we have gained an idea or two for making our own homes happier. If our reading will do this for us, if it will help us to see the romance of everyday life, it will perform a very big service, and be of immense value to us as a pastime. (Secretary, Mrs. H. Cummings.)

August 9th.—Present: 29 members.

CAKE RECIPES.—The following recipes are those of cakes which were exhibited at the August meeting:—*Nut Cakes with Dates* (Mrs. Hawke): 1 cup butter, ½ cup sugar, 1 egg, 1½ cups flour (heaped), ½ teaspoon each of ground cinnamon and bicarbonate of soda, 1 tablespoon boiling water, ¾ cup chopped dates, ¾ cup nuts. Dissolve soda in boiling water, add dates and nuts last; bake like small rock cakes in a moderate oven. *Coffee Sponge* (Mrs. W. Symonds): 3ozs. butter, 4ozs. sugar, 3 eggs, ½lb. self-rising flour, 2 tablespoons coffee essence, ½ cup milk. *Walnut Loaf*: 3ozs. butter, 3ozs. sugar, ¼ cup milk, 1 cup self-raising flour, 1 egg, ½ cup walnuts; bake in a greased loaf tin about 15 minutes. When cooked spread with chocolate icing, sprinkle with coconut and decorate top with walnuts. *Peaches* (Miss P. Moore): 2 eggs, ½ cup sugar, 2ozs. butter, 1 tablespoonful orange juice, 1 tablespoon milk, 1 cup self-raising flour; bake in gem scone trays. Cut tops off level and use cream filling. Paint lightly with cochineal and roll in castor sugar. *Milk Sponge* (Mrs. Parrington): 3 eggs, 1 cup sugar, 3 tablespoons butter, 1½ cups self-raising flour, 3 tablespoons milk; cream the butter and sugar; add the eggs, which have been beaten separately for five minutes; add sifted flour and milk. Bake in sandwich tins for 15 minutes in moderate oven. *Sandwich Filling* (Mrs. Orchard): ½ cup sultanas, ½ cup cold lamb, ½ cup almond kernels, put through mincer; add ½ teaspoon salt, and make a spreading consistency with a cooked mayonaise. *Chester Cakes* (Mrs. F. Cummings): Crumble stale cakes into a basin (if plain add a few currants and lemon peel), add a little melted butter and mixed spice, then mix to a soft consistency with milk. Roll out some rough puff pastry; spread the mixture on half and cover with the remainder of the pastry; mark into squares and bake in a quick oven. When cold ice with thin icing and sprinkle with cocoanut or brush over with white of egg and sprinkle with sugar before baking. *Cocoanut Macaroons* (Mrs. White): Whites of 2 eggs beaten well, add one cup sugar and beat again, then add 2 tablespoons desiccated cocoanut; drop on to a tray and bake in a very slow oven. *Kitchener Buns* (Mrs. Haskard): 1lb. flour, 2 tablespoons butter, 2 tablespoons sugar, 3 eggs, 2 tablespoons yeast; beat eggs and sugar; melt butter and add enough milk to mix to a dough. Set in a warm place overnight. Beat down and form into buns; let rise again for 1 hour. Fry in deep boiling fat. *Banana Tartlets* (Mrs. Brookes): 3 bananas, 1 orange, sugar; line patty pans with short pastry. Peel and mash the bananas with a fork, squeeze orange juice over them and sprinkle with sugar to taste. Fill patties with this mixture and bake in a fairly quick oven. Sprinkle with pink sugar. *Date Loaf* (Mrs. Bayly): 1½ cups sugar, 2 eggs, pinch salt, 1 cup walnuts, 2 teaspoons carbonate soda, 1 tablespoon melted butter, 2¾ cups plain flour, 2 cups chopped dates, 1½ cups boiling water; place chopped dates in a basin and pour boiling water over and allow to stand; cream butter and sugar, add eggs, flour, soda, and salt, then the walnuts, and lastly dates and water. Bake 1 hour in slow oven. *Jellied Marmalade* (Miss Mitchell): 3 poorman's oranges and 9 sweet—about 4lbs.—cut finely, and to every lb. add 3 pints water. Stand all night, boil till tender; weigh again and allow 1½lbs. sugar to every lb. Boil (galloping) for about 40 minutes or 1 hour, until it jellies. *Brownies* (Mrs. Moore): 2½lbs. flour, 1¼lbs. golden syrup, ½lb. sugar, ¼lb. lard, ¼lb. butter; melt butter, lard, and golden syrup; add sugar and 2 eggs, well beaten; add flour, in which mix 1 teaspoon ground cloves, 1½ teaspoons ammonia, 2 teaspoons carbonate soda; roll out ¼in. thick, put on slide, brush with beaten egg and put almonds at even intervals (about 2in. apart). Bake in a moderate oven; while hot cut into squares. *Lemon Cake* (Mrs. Richardson): 2 eggs, 2 tablespoons butter, ½ cup sugar, few drops of essence lemon. Beat butter and sugar to a cream; add eggs, one at a time, beating well; add essence and lemon peel; add 1½ cups self-raising flour. Bake in slow oven. Decorate with chocolate icing and walnuts or butter icing and raspberry jam. (Secretary, Mrs. F. Cummings.)

GLADSTONE (Average annual rainfall, 16.82in.).

July 8th.—Present: 20 members.

The meeting took the form of exchanging chosen recipes. *Lentil Soup* (*Mrs. H. Alvey*).—3½ pints cold water, ½ cup lentils, ½ cup haricot beans, 2 potatoes, 2 onions, little chopped parsley, pepper and salt to taste, ½ pint milk, 1 tablespoon butter. Wash beans and lentils well and soak overnight, boil slowly 3 hours or more, adding parsley, milk, and butter 10 minutes before taking up. *Anchovy Paste* (*Mrs. W. Thomas*). —Three red herrings, ½lb. butter, little cayenne pepper; mince herrings through mincer two or three times, then mix butter and pepper all well together and cork tightly. *Raspberry Pudding* (*Mrs. Gravestock*).—1½ cups flour, rub in ¼ cup dripping, ½ cup sugar, 2 tablespoons raspberry jam, mixed well with ½ cup milk, adding 1 teaspoon carb. soda. Steam two hours. *Preserved Ginger* (*Mrs. A. E. Pinch*).—Take any number of small oranges, choose thin skin and all about the same size. Grate them to make porous, put them in rainwater for three days, changing water twice a day. Take out, pull out stem end, and boil two hours in last water. Prepare syrup, weigh oranges, put little more than half weight in sugar, and little more than ½ pint neat to each ½lb. sugar. Re-boil few minutes and strain, and put in oranges and boil two hours until a nice yellow jelly is formed. *Eggless Cake* (*Mrs. S. Gillis*).—Two cups sugar, 2 cups water, 2 tablespoons butter, lemon peel, 1lb. fruit (either currants, sultanas, or dates), boil for five minutes, let cool, and add 4 large cups S.R. flour with 1 teaspoon C. soda, cinnamon, and allspice. Bake one hour. *Sponge* (*Mrs. F. Diener*).—Beat 4 eggs a little, add ¾ cup sugar, beat until you can print figure 8 with whisk, add 1 cup plain flour (sifted twice), and essence. Mix ½ teaspoon soda and C. tartar and add last, cook 10 minutes in moderate oven. *Pork and Beans* (*Miss Stephenson*).—1lb. haricot beans, ½lb. fresh pork, ½ cup tomato sauce, salt. Soak beans 24 hours and boil quickly 20 minutes with little soda and just covered with water. Cut up pork into small discs. Put beans into dish and the pork on top, add sauce and salt, cook slowly two hours and serve with buttered toast. *Method to Make Steak Tender* (*Miss Stephenson*).—Rub olive oil either side of steak and hang, then roll in greaseproof or brown paper to take oil out; steak is ready for use. *Eggless Pudding* (*Mrs. G. Smallacombe*). —Butter size of an egg, 1 cup sugar, 2 cups boiling water, 2 cups plain flour, 1 teaspoon carbonate soda, fruit to taste, steam three hours. *Spiced Steak* (*Mrs. H. Alvey*). —1lb. beef steak, ½ spoon each salt, sugar, ¼ teaspoon pepper, ½ tablespoon each of vinegar and tomato. Cut steak into disc, sprinkle flour over, add other ingredients, and blend well. Bake slowly one and a half hours. *Puff Paste* (*Mrs. Diener*).—1 cup plain flour, make hole in centre and put in yolk of egg and juice of ½ lemon and ¾ cup of water. Do not have mixture stiff, and roll out twice. *Nut Loaf* (*Miss M. J. Sargent*). —Mix together 1 cup self-raising flour, 2ozs. brown sugar, 2ozs. white sugar, add 5 chopped walnuts, 12 dates, cut up small, then 1 beaten egg, ½ teaspoon carbonate soda dissolved in enough milk to make a stiff paste. Bake in tall coffee tins for three-quarters of an hour in fairly hot oven. *Shrewsberry Biscuits* (*Miss M. J. Sargent*).—½lb. flour, 4ozs. sugar, 4ozs. butter, 1 egg, flavoring or 1 teaspoon lemon juice, cream butter and sugar, add egg and 1 tablespoon flour, then add remainder of flour gradually. Mix with hands, roll into little balls, and dip in sugar. Place on greased slide and press flat with prongs of fork, both ways. Bake 15 minutes. (Secretary, Miss M. Sargent.)

KALANGADOO (Average annual rainfall, 32.30in.).

July 9th.—Present: eight members.

QUESTION BOX.—Would the addition of lard to tallow have a detrimental effect on soap?—Answer: Members thought it would have a tendency to make the soap soft. Why is nutbread holey in the centre?—Answer: It was thought that the rising was at fault. What is the cause of bread sticking to the tin?—Answer: Because the bread dough is put in too wet; the dough should be well floured as well as the warmed tin. What is the cause of hard, white spots on sheep liver, and is the liver wholesome?—Answer: The liver is the most susceptible to all complaints, and if the sheep is not healthy it shows first on the liver, and is not wholesome. How to remove iron rust from linen?—Answer: Apply salt and juice of lemon to the spot; more than one application may be required. How to refoot socks that have not been knitted?—Mrs. Messenger gave a description of the shape required for refooting. What will remove olive oil marks?—Answer: Mrs. Brooks suggested starch made into a paste with cold water and left until dry then brushed off; probably more than one application would be required. (Secretary, Mrs. E. Dowdell.)

KANGARILLA.

July 21st.—Present: seven members.

HOUSEHOLD HINTS.—The Hon. Secretary (Mrs. M. Steer) read the following short paper:—If a sprinkle of icing sugar is mixed in the flour it will make scones very light.

When making Lamington cakes, instead of the usual icing, try jelly set to the consistency of honey, then roll in cocoanut in the usual way. When stewing prunes, add a large tablespoonful of honey instead of sugar. Add a tablespoonful of peanut butter to any biscuit recipe; this gives a nice nutty flavor. In recipes where sugar is used—particularly in puddings—try using half the quantity of sugar and a tablespoonful of honey. The flavor is delicious, and is more economical than all sugar. If unbleached calico is to be whitened do not put it into bluewater. Save all paper bags; it is easier and quicker to put an article into a bag than to make a parcel of it. The pulp of an orange gives a delicious flavor to stewed apples. The peel and pips of an orange or lemon contain tonic properties. Soak in cold water overnight and drink the liquid in the morning before breakfast.

McLAREN FLAT.

July 7th.—Present: 16 members.

Members contributed recipes and samples of small cakes. *Cakes.—Dreams.*—3 eggs, their weight in sugar, butter, cornflour, 2 teaspoonfuls baking powder; bake in pattypans for seven minutes in quick oven. Also makes nice loaf cake. *Orange Cakes.*—3 eggs, their weight in self-raising flour, weight of 2 eggs in sugar and butter, grated rind and juice of small orange, few drops of essence lemon. *Method.*—Cream butter and sugar, add well-beaten eggs, then flour, juice, and rind. Put teaspoonful of mixture in each patty, bake in moderate oven till golden brown; when cold take piece out of each cake, fill with whipped cream with squeeze of orange juice, sifted icing sugar to decorate. *Cocoanut Cakes.*—2 eggs, 3 tablespoonfuls sugar, 2 tablespoonfuls butter, 3 tablespoonfuls cocoanut, 6 tablespoonfuls self-raising flour. *Method.*—Beat sugar and eggs, then butter, cocoanut, and flour; bake in moderate oven 10 to 15 minutes. *Lamingtons.*—½ cup butter, 1 cup sugar, 2 cups self-raising flour, 3 eggs, little flavoring. *Method.*—Cream butter and sugar, add eggs well beaten, then sifted flour; bake in moderate oven. When cold cut into small squares, dip in chocolate icing, then sprinkle cocoanut all over. *Betty Cakes.*—3ozs. butter, 3ozs. sugar, 6ozs. self-raising flour, 1 egg, 4 tablespoonfuls milk, 1oz. currants. *Queen Cakes.*—¼lb. butter, 1 cup sugar, 1½ cups self-raising flour, 2 eggs, flavor with essence lemon. *Margaret Cakes.*—¼lb. butter, ½ cup sugar, 2 eggs, 1 tablespoonful milk, juice and rind orange, 1½ cups self-raising flour, ½ cup cornflour. *Method.*—Cream butter and sugar, add beaten eggs, add flour alternately with juice and milk. Put in small containers, bake in moderate oven 10 to 15 minutes. When cold brush over with apricot jam and sprinkle with cocoanut.

COOKERY HINTS (by Mrs. B. Elliot).—In making pastry for roly-poly it is better to add 1 cup of breadcrumbs to 1 cup flour, instead of making paste all flour. Gingerbread, and cakes with treacle or honey, are liable to burn easily, and so require a moderate heat. To keep cheese from moulding or from becoming dry, wrap it in a cloth, damp with vinegar, and keep in a covered dish. When making boiled puddings of any kind try putting a piece of greased paper over the top before the cloth is put on. This renders the cloth much easier to wash, and keeps the pudding nice and firm. To serve green vegetables really green, cook without lid on saucepan. Too rapid boiling spoils and makes most vegetables tough. Put a few grains of rice into salt shakers to keep salt dry; the rice absorbs the moisture from the salt. To stone raisins, put them into a warm stove on paper, leave door of store open; when raisins get warm, squeeze out the stones. To cut new bread, first dip the knife into boiling water; repeat when cool. To cover jams, &c., use soft tissue paper dipped in milk; put it over the jam at once, when the heat will dry it, making it like parchment. Put about the size of an egg of breadcrumbs tied in muslin with the cabbages when cooking. Cabbages cooked like this may be used in any way. The bread absorbs the bitter juices, also absorbs almost all smell while cabbage is cooking. Cakes will be much lighter if mixed with the hands than if a spoon or knife is used. Icing for cake may be prevented from cracking when cutting by adding 1 tablespoonful of sweet cream to each unbeaten egg. Save stale bread scraps, dry them thoroughly in an open stove, and then crush with a rolling-pin as fine as powder. These will always be at hand for preparing cutlets and fish.

Economy Hints.—A pinch of carbonate of soda added when stewing fruit saves sugar. For dried fruit, soak overnight with enough cold water to cover fruit, add a little soda; this makes the fruit a more natural color. With mashed potatoes use hot milk, and butter will not be needed. When frying fat is past use for cooking purposes, convert it into soap, or collect and sell to soapmakers. Save all scraps of soap, tie in a muslin bag, put into boiling water for a short time, then plunge into cold water. This will cause the soap to harden again in one piece. Enamelware will not readily crack or chip if it is put in a large pan of cold water, brought slowly to the boil, boiled for 15 minutes, and allowed to cool in the water before using. Glassware treated in the same way is less likely to crack.

Household Hints.—Cut flowers may be kept fresh by putting a spoonful of powdered charcoal into the vessel. Do not change water. To remove grease from a stove, try this plan:—Dip a cloth in dry soot, and rub this well over the greasy parts, then apply blacklead and the spots will at once disappear. Newspaper can also be used to remove grease spots, using it before the polish. *To Remove Match marks.*—Rub with piece of cut lemon, and afterwards with a rag dipped in water, and the stains will disappear. When filling a kerosene lamp, drop a dessertspoonful of salt into lamp; it makes the lamp burn much brighter.

PARILLA (Average annual rainfall, 13.91in.).

June 16th.

Cake Making Competition.—The following are the awards in the very successful cake making competition organised by the Branch:—Collection of sponges: First, Miss Phillis; second, Mrs. Dabinett. Sultana, currant, seed, and coffee cakes: First, Mrs. Neindorf; second, Mrs. Foale. Napoleon, gingerbread, ribbon, and Dolly Varden cakes: First, Miss Phillis; second, Mrs. F. Kerley. Collection of small cakes: First, Mrs. R. C. Kerley; second, Miss Phillis. Scones and coffee rolls: First, Mrs. Niendorf; second, Mrs. Colwill. Nut bread: First, Mrs. H. G. Johnston; second, Miss Phillis. Cream puffs: First, Miss Colwill; second, Mrs. Brown. Four varieties of pastry: First, Miss Phillis; second, Miss Colwill. Bread and bread rolls: First, Mrs. Welden; second, Miss Phillis. Yeast cake and buns: First, Miss Phillis; second, Mrs. Welden. Collection of biscuits: First, Mrs. R. C. Kerley; second, Miss Colwill. (Secretary, Mrs. R. Welden.)

PARILLA WELL (Average annual rainfall, 14.04in.).

June 21st.—Present: 21 members and five visitors.

The meeting took the form of a Cake Exhibition, and in some sections there were quite a number of entries. A small entry fee was charged, part of the proceeds being set aside for prizes. Mesdames Young & Hawthorne adjudicated. Those gaining prizes were as follows:—Dark Fruit Cake—1st Mrs. Beckman, 2nd Mrs. Holmes; Sultana Cake—1st Mrs. Holmes, 2nd Mrs. N. Venning; Coffee Cake—1st Mrs. M. Davis, 2nd Mrs. R. Billing; Light Sponge Cake—1st Mrs. B. Pahl, 2nd Mrs. M. Davis; Ribbon Cake—1st Mrs. Gent; Brown Sponge—1st Mrs. Beckman, 2nd Miss J. Blacksell; Swiss Roll—1st Mrs. Blacksell; Small Cakes (6 varieties, 3 of each)—1st Miss E. Pahl, 2nd Miss V. Ireland; Nut or Fruit Loaf—1st Miss B. Johnston, 2nd Mrs. Gent; Plain Scones—1st Mrs. N. Venning; 2nd Miss Blacksell; Best Collection of Pastries—1st Mrs. Holmes, 2nd Mrs. Slater; Cream Puffs—1st Mrs. B. Pahl, 2nd Miss B. Johnston; Biscuits (6 varieties, 3 of each)—1st Mrs. Gent, 2nd Mrs. Wurfel. An invitation was extended to the men's Bureau, and a dainty supper was handed round. (Secretary, Mrs. S. Flint.)

PENOLA (Average annual rainfall, 26.14in.).

July 6th.—Present: 18 members.

Question Box.—How to pot butter?—The best time to pot butter is in spring. Mix equal quantities of salt, sugar, and saltpetre. Mix together and roll out very fine; squeeze out all surplus water, and mix 1oz. of the mixture to every pound of butter. How to make butter soft in winter?—Wash butter in warm water, and add small quantity of hot water to the cream before churning. Why is pastry hard when cooked? —This is often due to the oven not being sufficiently hot, and also by adding too much liquid. Pastry is made lighter by adding a little lemon juice, or by adding the beaten yolk of an egg. Bake in a very hot oven. Why do cakes have a coarse appearance and have holes in when cooked?—Too much rising has been used. Sponges especially need little rising. Should cold or boiling water be used for cooking beetroot?—Putting the beetroot into cold water was said to be the general method used, but some members thought boiling water and long cooking were essential for preserving both coloring and flavor. How to make a dark chocolate sponge?—Add a little caramel to the cocoa —only very little. Bourneville cocoa has been found excellent to give dark coloring. Why do mustard pickles shrink after being pasted down for some time?—The remedy is to press pickles well down, and add plenty of liquid, so that there is a depth of liquid above the pickles. Best method of straining jelly?—Some members use flannel, tea towel, and others cheesecloth. (Secretary, Mrs. E. Kidman.)

TANTANOOLA.

August 3rd.—Present: 16 members.

Making Foot Stools.—Mrs. Edgecumbe read the following paper:—"Procure any kind of tins, but for each floor cushion it is necessary to have all tins of exactly the same kind. To make a nice size cushion it takes seven 2lb. treacle tins; another nice shape is with nine honey, health saline, coffee, or any small size tins. The following material is required. Scraps of different material, or, if required, the one piece cardboard and wadding for padding. The centre tin can be covered with any old piece of rag, but it must be covered. Place the tins together for the desired shape; then proceed as follows: Cover each tin with material such as cretonne or velvet. Place all together and sew across the tops of the tins to connect them together. Turn upside down and do the same with the bottom. When covering the tins, leave about 1in. top and bottom longer than the tin, to turn over and sew. Place on a piece of cardboard and draw around the tins. Get two pieces of cardboard—one each for top and bottom. Cover these with material and sew one on the bottom of the tins. Place padding on top of tins and sew the other cover on top. Having completed this, sew some cord around the tins on the top.'' (Secretary, Mrs. E. Telfer.)

WARRAMBOO.

June 17th.—Present: six members.

Bacon Curing.—Mrs. F. Chilman read the following paper:—The making of really first-class bacon first depends on having the right class of pig to kill. The Large White is recognised as being the very best—having a long side and fine-textured meat without coarseness—but a long-shaped pig is always better for bacon than a short, thickset one. Correct feeding, too, is most important. Provided a large quantity of feed is available it is an easy matter to load a pig with fat, but as most people prefer streaky bacon the pig should be fed to develop lean as well as fat. A fair amount of milk in the ration is the best means to this end; where milk is not available meat meal should be given. As to size the best bacon is made from pigs weighing from 120lbs. to 150lbs., and if reasonably well fed a pig should dress that weight at from 20 to 24 weeks. The bacon of a larger and older pig is more cumbersome to handle as well as being tough and fibrous, and the fat is more greasy. The pig should not have either feed or water for at least 24 hours before killing, and the weather is all important. Pork is far more susceptible to thunder or warmth than any other meat, and bacon prepared in very wet weather is seldom a success however cold. In cutting up a pig—especially a fairly small one—it is best to leave practically all the side meat on the bacon, leaving the ribs bare. The hams should be trimmed to a nice shape, and the top or hip bone removed. This leaves the next bone with a knob on the end of it. Saw this bone off about 2in. below the knob, then push the steel into the remainder to squeeze out the marrow. This is a very necessary precaution because the marrow inside the bone is where the taint or decay begins, and this method does not spoil the appearance of the ham, as does removing the whole bone. I prefer dry salting for pork rather than brine, and to 7lbs. of salt allow two cups sugar, and a full tablespoon of saltpetre. The saltpetre gives the meat a nice color and helps to preserve it, but too much makes it hard and indigestible. A large fly-proof box with a wire gauze cover makes an ideal receptacle for curing, but it is very necessary for the liquid that the salt drains out to be able to leak away. The meat should be turned and re-salted every second or third day, and at the end of a fortnight—slightly more or less according to the size of the pig—it should be cured, and the bacon ready to roll. Bacon, unless very large, should always be rolled. It is well worth the extra trouble; it holds its flavor and prevents drying out. To prepare for rolling, the bacon is laid out on the table and very thoroughly dried on both sides with a soft cloth; any moisture is likely to cause mould inside the roll. If a spiced bacon is liked, almost any kind of spices, whole or ground, may be added at this stage, by being sprinkled over the flesh side before rolling. Crushed cloves and nutmeg give a very nice flavor that penetrates all through the flesh, or ordinary mixed spice may be used; this is entirely a matter of individual taste. The actual rolling is a task that calls for a good deal of strength, because the more closely and firmly it is rolled, the better, always commencing from the thickest side. Binder twine is the best for tying—it grips better than string, and the tying is not so hard on the hands; the ties need to be about 2in. apart. The bacon is then ready to hang up, and may be used at once, but is much improved by hanging for two or three weeks to mature. (Secretary, Mrs. A. Collins.)

SOUTH-EASTERN.

TATIARA (Average annual rainfall, 19.39in.).

Question Box.—The June meeting was arranged as a Question Box night, and proved to be popular with members and provided excellent entertainment and not a little instruction. There was a good muster of members in attendance and Mr. H. Fisher presided. After formal business Mr. F. Meier gave a demonstration with weights and other apparatus of tractive resistance in relation to horse swings. The demonstration was the outcome of a contention at the previous meeting of the Branch on the question whether heavy swings had an advantage over light ones. Mr. Meier held that, once the swing was suspended its weight was negligible, and that heavy swings exerted a tractive influence upon the implement being drawn. Mr. H. Bond opposed this theory and contended that the heavier the swing the greater the load to be drawn by the team. It was to prove his theory and strengthen the case for heavy swings that Mr. Meier gave the demonstration, for which he received the thanks of the meeting. The first question drawn from the box was: "Has Subterranean clover been a success in this district?"—Mr. R. Hunt said that on light land it was a success, but on limestone and black clay lands it was a failure. Mr. H. Bond considered it was not a great success in this district; natural clovers had proved superior on most local holdings. "Should a farmer in this district send his wool to Melbourne or Adelaide?"—Mr. H. Exton pointed out that returns were always earlier from Melbourne; Mr. R. Hunt favored Adelaide because freight to that market was cheaper. "Is the Corriedale-Merino cross an improvement on the pure Merino?"—Mr. F. Milne preferred pure breeds. Mr. Bond considered that the Corriedale was a better sheep for fattening than the Merino; it also grew bulky, though light fleeces of good quality; Corriedale-Merino lambs, under 12 months old, dressed up to 74lbs. weight. "Do you think the tractor has been a good investment for agricultural purposes?"—Mr. E. Grosser did not think it had; Mr. R. Hunt favored the tractor, but considered that the ideal thing was a tractor and a good team of horses. "Can pig-raising be made profitable in this district at present?"—Mr. E. Fisher was emphatic that at present market rates it could not; rail freights were prohibitive. This opinion was endorsed by Mr. F. Densley, who cited the case of a local man who had recently sent six good porkers to the Adelaide market and, after deducting feeding costs and freight he cleared 1s. on the lot. Mr. E. Grosser said that 120lb. pigs were worth as much as heavier pigs at Murray Bridge sales. "What do you think is the best quantity of feed to give a horse?"—Mr. Densley believed that a horse should be given feed according to its appetite—as much as it will eat. Mr. F. Milne preferred quality of feed, before unlimited quantity of coarse feed. Mr. A. Milne considered that feeding should be regulated. The general opinion of members was that each feed should be eaten before another was given; more oats should be used in the feed. "What is the best method of treating a paddock sown with oats for hay, that at present is very cloddy, and on which neither combine nor harrows are effective?"—Rolling was the suggested treatment. (Secretary, L. Butler.)

UPPER-NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

WARCOWIE (Average annual rainfall, 11.42in.).

July 6th.—Present: 14 members.

FALLOWING.—The following paper was read by Mr. R. Jarvis:—"Fallowing is one of the essentials in making wheat growing a success. It should be started as soon after seeding as possible, when the ground is wet, because early fallow generally grows the best crop, especially if one has the time to work it over in spring or soon after harvest. Rough fallow should be harrowed before seeding, otherwise some of the grain will be buried too deeply. The mouldboard plough is the best implement for fallowing. Nothing is gained by fallowing with a combine or spring tooth cultivator, because these implements will not kill all the large weeds. The soil should be ploughed from 2½in. to 3in. deep. New ground requires deeper ploughing because it is more uneven, and the low patches are likely to be missed with the implements."

DESTRUCTION OF RABBITS.—"The best time to deal with rabbits is in summer, when the feed is dry," said Mr. H. Sanders, in a paper on this subject. "They are then looking for food that contains moisture, and will readily take moist pollard mixed with poisons. At this time of the year the fumigator also will give better results. The poison cart is also useful, and the best time to lay the baits is just after a rain. A good bait for rabbits is a head of wheat dipped in strychnine. Grind the strychnine to a fine powder, make a slack paste of pollard and water and mix the strychnine well into it. Dip the heads into this mixture and place them along the edge of a wheat crop where the rabbits are troublesome. Trapping is another good method, but it is too slow. One week in summer with a good fumigator is worth a month's trapping in winter. Chaff and sulphur will kill the rabbits in their warrens. When trapping pick in all the holes, then after a few days set the traps at the holes that have been opened. I prefer the box trap because it can be covered easily and quickly." (Secretary, A. Crossman.)

MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

MURRAYTOWN.

June 18th.—Present: 11 members.

SHEEP AS A SIDELINE.—Mr. W. Joppich, in the course of a paper on this subject, considered that on a 640-acre farm there should be 150 to 250 sheep carried, of which 60 per cent. should be breeding ewes. One hundred and fifty sheep with wool at 8d.

a pound should return £45 per year for wool, or 15s. a week. He preferred to go through the sheep at shearing time and mouth every sheep. Any with broken mouths should be marked for rations or market. In the discussion which followed Mr. Tregenza said it was difficult to keep the fallows clean without sheep. He thought more sheep necessary than the number mentioned. He asked Mr. Joppich as to whether it was not better to use rams of English breeds for rearing of lambs. Mr. Joppich replied that where plenty of feed was available it was a good idea to produce cross-bred lambs, but they had the drawback of producing coarse wool. Mr. Clogg thought the suggested numbers of sheep about right for the size farm spoken of, though at times there might be feed available for double the number of sheep. Mr. Joppich was asked if he thought it advisable to brand sheep twice a year. This was not considered necessary for big sheep, but it might be advisable for lambs where there was a tendency for the brand to disappear in the spreading of the wool. Mr. Joppich preferred to brand sheep on the rump. Mr. Borgas said that the owner of a registered brand could use any figure from 2 to 9 on any part of the sheep. He preferred to brand on the shoulders; this was easier to see when running the sheep through a race. Mr. Joppich asked members what they preferred to use as a dressing against fly troubles. Mr. N. Scholz said a good mixture was half kerosene and half Stockholm tar.

At a further meeting held on July 16th the Hon. Secretary read a report of the work of the Branch during the past year.

On June 21st Mr. C. A. Goddard, of the School of Mines, gave an address, "Wool Classing." (Secretary, E. Pitman.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

BRINKWORTH (Average annual rainfall, 15.74in.).
June 13th.—Present: Nine members.

How to Farm Successfully.—Mr. H. Ottens read the following paper:—"This is a problem affecting every farmer at the present time. Owing to the collapse of the world's markets, and adverse climatic conditions experienced during recent years, fully 50 per cent. of the State's farmers are faced with this problem, without any apparent solution. It is frequently stated that the only hope lies in mixed farming, but all livestock necessary for this method are being sold at values far too high relative to returns which may be expected, and it is difficult to see how that will improve the situation. It must be realised that the farm requires the whole of your attention, both physically and mentally. Sport and pleasure must for the present be set aside, and should on no account be allowed to interfere with farming activities. Every farmer should be constantly on the alert for any way in which any operation can be carried out at less expense or improved on, and every avenue explored for any leakage and promptly remedied. Purchase of new machinery should be avoided; that old machine can be repaired with a few pounds' worth of spare parts, a little time and patience, or, if other machinery is essential, shrewd second-hand buying is the better business proposition. When working machinery, an observant eye should be kept for missing bolts, &c., and these must be immediately replaced; this will eventually save both time and expense. The old adage, "A stitch in time saves nine," is as true to-day as when it was first used. If working horses, remember that they are only capable of doing a given amount of work a day; if pushed beyond this limit a reaction will soon set in, and one will not accomplish any more, and, in addition, the team will be worn out. Generally speaking, a tractor farmer has to exercise more care and forethought than the horse farmer, and if this is not used to the fullest extent calamity will surely occur. A very important factor in successful farming is to have a plant commensurate with the amount of work to be performed. If the plant is too small, losses will result through unseasonable tillage; if too large, overhead expenses will be too high. A special warning is needed against working both tractor and horses, unless the holding is of sufficient size to warrant doing so. Every farmer should keep in touch with the latest scientific developments, and for this purpose should be a member of the Agricultural Bureau, because through this medium he can be kept in touch with the latest scientific developments. However, the most important point towards being a successful farmer is, before purchasing anything, either land, machinery, or livestock, to obtain reliable information concerning same, and after deliberately weighing all evidence, fix a price which is considered a sound business proposition, and, if below prices ruling at the time, refrain from purchasing. The sooner it is realised that the present method of arriving at values per medium of recent sales is absolutely erroneous the better for the farming community generally. Finally, by looking a few years ahead and shrewdly anticipating stock prices, every farmer could save a large amount of money—present purchasers of horses will realise this—and it is evident during this period that the advantages of the seller over the buyer are considerable." (Secretary, H. E. Ottens.)

CURRANT GROWING IN THE CLARE DISTRICT.

The following paper was read by Mr. W. H. Penna, of the Penwortham Branch, at a meeting held on June 15th:—

"The growing and treatment of currants in the non-irrigated areas has not been given that care and attention which should enable growers to obtain full production from the vines.

The last few years have not been very encouraging to growers; prices have been below cost of production, with the result that many growers have had to explore other channels, and, in doing so, have not been able to give sufficient time and labor to their vineyards. In such cases, the ultimate result will be weak and immature wood, the condition of such being the deciding factor in a heavy or light crop.

The currant industry is one of the main assets of the Clare district. At the present time there are under currants 1,475 acres, the highest tonnage produced being 1,120 tons. Last year 630 tons were produced, averaging about £25 per ton, giving to the district £15,750. This year the tonnage will be about the same, but prices have improved considerably, and should average about £10 per ton more, the district therefore benefitting by an additional £6,300. This industry also has to its credit the fact that it is one of very few primary industries that has not been assisted by the Government. During the period of stress through which it has passed its battles have been fought and won through its own organisation, with the result that to-day it is recognised as the best organised primary industry in Australia.

There are many factors to deal with which influence the quality of the dried produce, one of the most essential being pruning. Pruning stands unique in the execution of its work by the adoption of so many different ideas and systems applied. Firstly, a good sharp pair of secateurs is essential for clean and neat cutting. Observe each vine, and note whether it has made strong or weak growth, and prune accordingly. In pruning a strong growing vine, do not overtax its strength by leaving too much wood, the result being spoilt fruiting wood the following year. Always try and keep the spurs as near the main arm as possible in order to be near the main flow of sap. As to the length of spurs, two clear eyes and the base bud are advised. In selecting the spur it is essential to take into consideration its condition. If the first shoot next to the base is strong and healthy, always spur it for fruit. If this shoot is not strong enough for fruitbearing, and the top one is strong and vigorous, make this the fruiting spur, but do not overlook the fact that it will be a considerable distance from the main arm. Overcome this by leaving a reducer as far down the spur as possible to come back to the following year. Very often strong water shoots come out from the main arm, and, if in a good position to take the place of an old spur, do not fail to make a reducer of same. Always cut reducers to one eye, but the following year do not leave both the reducer and the old spur for fruit. Many light crops and small bunches are due to poor selection of fruiting wood. It is asking the impossible to expect a weak, immature spur to produce good quality fruit. Some will say that at times one has to sacrifice some of the crop to keep back the spurs, but quality is essential, and it can only be obtained from strong, healthy spurs. Have the spurs as near the top of the main arm as possible, or, if on the side, have them evenly distributed on both sides, so that when the foliage and fruit are on the vine it will be evenly balanced, not allowing the trellis to lean one way more than the other. The treatment of the terminal rod—especially on young vines—is very important. The length to be left every year until the space between the vines is filled varies according to the growth made, and much harm can be done to a vine—even a strong growing one—by leaving the terminal rod too long. The outcome of this is that the wood produced from spurs joining the rod and following in to the centre of the vine is considerably weakened, and in many cases dies out, necessitating cutting away a portion of the main arm the following year to force stronger growth. The length of the terminal rod on a strong growing vine should be about 2ft., the weaker the vine, lessen accordingly. The rod and spur system is one which will give abnormal crops for a few years, if used extensively; then for a few years the vines generally yield below normal. In using this system, the correct rod and spur should be selected from a last year's spur, which has produced two good healthy shoots, selecting the terminal shoot for the rod and the shoot next to the base bud as the spur. The following year, when pruning, always cut the old rod clean out, and work back on the new wood produced from the spur. This system of pruning is not used to the extent that it was a few years ago, the chief fault being that the rod in many cases smothers and weakens the shoots produced from adjoining spurs. Fruit also is generally smaller, and takes longer to ripen. Although not advocating the rod and spur system to be used to any great extent, this last three or four years the writer has used a short rod sufficiently long to tie down on the wire carrying the main arm, looping it as much as possible, and by doing this almost every bud shoots. This is only practised on vines making strong growth where there are not sufficient spurs to produce the quantity of fruit the vine should carry. This has given reasonably satisfactory results, although by comparing the fruit obtained from the rods with that from spurs for the last season the fruit produced from the latter was a little better. Nevertheless, good average crops and quality have been harvested, and the vines are in good heart. An important point which should never be neglected is the cutting out of all dead wood.

In summing up, each person who prunes his vines should—if he has the interest of his garden at heart, after a period of years—be the best judge in reference to its pruning. After years of cutting the removal of old spurs will necessitate large cuts, which do not heal over, and eventually cause part of the main arm to die. Many old vines are affected in this manner, and although the root system of these may be quite satisfactory, they are unprofitable. Many growers have made the mistake of leaving such vines clinging to them for only the few small bunches every year, whereas if a system of rejuvenation had been followed financial results would have been very much better. Such vines should be sawn off near the ground, which would force a new shoot —if one is not already there—meaning the loss of one crop, but giving practically a new vine, which will produce far heavier crops and better quality fruit. A great future

ROSEWORTHY AGRICULTURAL COLLEGE.

LIVESTOCK FOR SALE.

During the next few weeks the College can offer for sale the following animals from their well-known flocks:—

Berkshire Boars, from 8 weeks to 8 months old.
Berkshire Sows, from 8 weeks to 8 months old.
Berkshire-Tamworth Crossbred Sows.
Jersey Bulls and Bull-calves, from Tested Herd-book Cows.
White Indian Runner Drakes and Ducks.
White Leghorn Roosters.
Black Orpington Roosters.

— FULL PARTICULARS FROM THE PRINCIPAL. —

is ahead of the currant industry. Throughout the world-wide depression this industry has not only held its own, but has improved its position. This fact alone should urge growers to keep the industry in the position it now holds, and this can only be done by cultivating still more that spirit of co-operation in the growing and marketing of its products.'' (Secretary, A. Jenner.)

YORKE PENINSULA DISTRICT.

(TO BUTE.)

BRENTWOOD (Average annual rainfall, 15.54in.).
July 7th.—Present: 15 members.

Repairs.—The following paper was presented by Mr. H. Boundy:—''Before starting seeding see that all swings and chains are in good working order, The combine, being one of the main implements used during seeding, should have all worn parts replaced, a new set of shears, and it is always advisable to fit a new set of bolts if working in stony country. The harrows are very important in seeding time. They should be sharpened and straightened, because loose harrows miss a lot of ground and blunt ones only pass over the surface. The plough should have all the furrows straight, bolts tight in the feet, and a sharp set of shears ready for work. When seeding and fallowing are over, fences and gates should be mended; a few wires strained up at the right time saves chains of new fence during the year. The binder should be overhauled, the knife taken out and sharpened, and fingers tightened and closed down will make a considerable saving on the pitman. Good straps and buckles on the canvasses save much time and trouble. Headers should have the main working parts taken to pieces so that the bearings and spindles may be inspected. The threshers should be inspected and set ready to start on the barley crop. The combs should be taken off every three or four seasons, ground, thimbled, and reset to make a clean job. When harvesting is finished, collars should be relined. The man on the farm has to be a jack of all trades, because it would cost a very considerable sum of money if one had to take all repairs to the blacksmith, carpenter, and motor garage.'' (Secretary, E. Carmichael.)

WEAVERS (Average annual rainfall, 16.80in.).
July 11th.—Present: 12 members and five visitors.

Fallowing.—Mr. A. Cornish presented the following paper:—''Fallowing is a very important part of farm work. There are three distinct types of soil in this district: (1) grey loam, (2) heavy red ground usually interspersed with limestone ridges, and (3) sand. The two first named can be worked similarly although the red flats should be ploughed a little deeper than the grey loam. In these soils fallowing should be commenced as soon as possible after seeding, using a plough for the first breaking up of the soil and ploughing 2in. or 2½in. deep. The fallow should then be harrowed twice, crossing the ploughing as much as possible. Should the ground have broken up very lumpy, it should then be rolled with an ordinary land roller or cultipacker. The fallow should then be cultivated whenever a growth of weeds renders it necessary. I favor the cultivator for all subsequent working of the fallow; it tends to bring the clods to the surface and packs the fine soil into a firm seed-bed, free from air spaces, whereas the skim plough brings the fine soil to the top and leaves the seed bed in a looser condition, which allows of more evaporation. Harrows should be used whenever a crust has formed on the fallow, this breaks the connection between the surface and subsoil, thereby stopping evaporation. Care must be exercised in working the red ground to see that it is not wet enough to be boggy, or it will set too hard to work down nicely again. Sheep should be run on the fallow whenever weeds appear, for in addition to cleaning the land, they help pack the soil together and enrich the ground with their droppings. Before starting to fallow, it is advisable to have kept the sheep on the paddock as much as possible because a lot of weed growth prevents the soil from working down nicely. The sandy soil which is liable to drift should be ploughed later —about September—and cultivated once. In working the fallow it is advisable to cross cultivate it whenever possible, as when going the same way the tines follow the old track and so allow many weeds to slip past. More ground should not be ploughed than it is possible to work properly, and the fallow should be cultivated at least twice before harvest.'' (Secretary, H. Cornish, Stansbury.)

WESTERN DISTRICT.

CUMMINS (Average annual rainfall, 17.77in.).
June 10th.—Present: Eight members.

Barley Growing.—Mr. P. Vanstone, in the course of an address on this subject, said his first experience of growing malting barley was on Yorke Peninsula, and on fairly new land it proved a failure, but on old land ti did well. His experience in this district was similar to that on Yorke Peninsula as regards yields, also in that it did not affect the following wheat crop if it was old land. He sowed barley on burnt wheat stubble land, sometimes sowing the barley straight in with the combine, other times working the land over and sowing later. It made no difference to the subsequent wheat crop whether the barley stubble was burned off or not. He preferred not to burn it, and it made such splendid sheep feed, and when ploughed in served to keep the soil from binding. A good discussion followed, and Mr. Vanstone replied to numerous questions. Would sow three acres to a bag in early part of seeding, later sow thicker. About 60lbs. super was a fair dressing for barley. The heavy land was best for barley in this district. He preferred formalin for pickling. As regards selling barley, he thought it best rule to make early sales. (Secretary, H. Roberts.)

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

June 14th.—Present: nine members.

Fallowing.—Mr. R. Wake read the following paper:—"Fallowing is one of the most important parts of farming and also one of the most difficult to accomplish. It is important because it is a means by which farmers are enabled to increase their yields by many bushels per acre if properly done. In a very good season the difference in yields per acre is much less than in less favored seasons, as will be seen from the following tabulations—the State average.

	Crop grown on fallow.	Crop grown on land not fallowed.
1928-29	10¾bush.	3¾bush.
1929-30	9bush.	3bush.
1930-31	11bush.	4bush.
1931-32	14⅓bush.	7½bush.

The best crops are grown off early fallow, *i.e.*, fallow that has been completed before the end of the winter rains. By so doing the maximum amount of moisture is conserved and there is a better chance of killing weeds. Fallowing consists of three essentials: preparing a seedbed, conserving moisture, and killing weeds. In dry seasons when there is a short growth of weeds, the lighter ploughs and cultivators do effective work. In the better seasons of early rains, a considerable growth of weeds and bushes spring up, making it difficult to fallow unless the rubbish is kept down by sheep. The best implement to use for this is the mouldboard plough, which makes a level seedbed and turns the rubbish under; when the land is covered with bushes and

C. F. ANDERSON, Poultry Expert.

shrubs the disc plough does good work, and being lighter in draught than a mouldboard plough one can get over the ground more quickly. It does not pay to plough deeper than 2in. to 3in. because seedbed consolidation is difficult to obtain. The cultivation of the fallow is just as important as the ploughing. It is not advisable to cultivate these soils to a smooth surface, because the wind is almost certain to spoil the work. It seems quite necessary that the surface be left ridged during the windy period of the year. It would seem that too much cultivation prior to harvest leads to drift. The practice of most farmers is to work the land during spring and after that control the weeds by sheep. If cultivated when the soil is moist, there is less tendency for it to drift and less loss of moisture. Given the right conditions, working fallow between harvest time and seeding seems to have a very beneficial effect upon the soil, especially is this noticed if rain falls at the end of summer or early in autumn. Rain is the real consolidating factor, and farmers should try to work the fallow as shallow as possible with effective destruction of weeds. If all these things have been done well the fallow should be free from weeds and ready to grow a good crop of wheat.'' Discussion: Mr. Story only used a plough for fallowing when it was absolutely necessary. It was not wise to plough too deep. A crop of wheat sown on land ploughed deeply grew too much straw, whereas on shallow ploughing the reverse was the case. He was not a lover of the disc plough. Mr. Wills said ploughing the land brought about the aeration of the soil, which was assisting Nature in making an ideal loamy soil. A firm seedbed was one of the main things to have at seeding time, when a good germination would result. In different districts the land was ploughed at different depths. Mr. Wildman said rainfall had much to do with the depth of ploughing. There was no harm in ploughing deeply in a wet season. In dry seasons the land was too loose to allow of that being done. Mr. S. V. Wake said the combine had been all right in dry seasons, but now it was necessary to use the plough. It was a good opportunity to cope with the magnesia patches in the land. Mr. White noticed with interest the different depths farmers ploughed in different districts. In heavy black land 6in. was not uncommon, and in dryer districts 2in. was about the average depth. A good crop usually grew on an old roadway through a paddock. Mr. Cooper favored the plough, especially for heavy land. Deep fallowing was no good; 2in. to 3in. was the ideal depth. The disc plough may be all right in straw and rubbish. The combine was the ideal implement for seeding, because it placed the grain on a firm, hard seedbed. (Secretary, W. Cooper.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

BARMERA.

May; Present: 30 members.

Manuring Fruit Trees and Vines.—The following points are taken from an address by Mr. F. R. Arndt (District Horticultural Instructor):—Manuring was often an experiment for the individual blocker and needed common sense. All soils would not yield to similar treatment. Heaviest application of manures, also ploughing, should be done before the end of August. An average ideal system of manuring:—(*a*) Cover crop (peas or beans) together with heavy dressing of super (3cwts. per acre); (*b*) Before buds burst, give 2cwts. super, 1cwt. sulphate of ammonia; 1cwt. of blood and bone manure may be added, also 1cwt. of potash in sandy soil.

At the July meeting Mr. Arndt addressed blockers on ''Grafting.'' A profitable evening was spent, 50 members attending. The lecturer referred to ''Phylloxera,'' emphasising South Australia's practical immunity. Stock affinities did not pay so large a part in grafting as in previous days. The doradillo was a suitable stock for grafting sultanas, currants, malagas. Shiraz on doradillos did not do well. It was advisable to graft below ground level and too many vines should not be prepared ahead. The preparation of the scion was outlined in detail, and a ''live'' model did much to drive home the lecture. Mr. Arndt thought it advisable to graft in early September after the first rush of sap had taken place. Layering and whip graft were explained, and also the yema or summer bud. (Secretary, C. Till.)

ALAWOONA FIELD DAY.

The Alawoona Branch of the Agricultural Bureau took advantage of the presence of officers of the Department of Agriculture in the district and arranged a tour of inspection of farms in the vicinity of Alawoona. Six car loads of members, in company with Messrs. W. J. Spafford, H. B. Barlow, R. L. Griffiths, P. H. Suter, and F C. Richards, of the Department of Agriculture, took part in the tour. Leaving the Institute at 11 o'clock the first property to be inspected was that of Mr. T. Willson, who, before coming to Alawoona in 1914, was engaged in farming operations on Kangaroo Island.

e recalled the time when crops were cut with a sickle, and the stir that the first ornsby binder created when it was brought to the Island. His present holding, which s all fenced and consists of 1,514 acres, all of which is cleared except 100 acres. This year he has under crop 500 acres—400 acres being wheat fallow and 100 acres of oats. A crop of Rajah on present indications is expected to yield 15bush. to the acre. The outstanding feature of Mr. Willson's property is the fine vegetable and fruit gardens. From the fruit garden, which was planted nine years ago, he expects to gather 30 cases of fruit, including apricots, peaches, nectarines, plums, and apples. Other than a bucket of water given to each tree when it was planted, the trees have not received any watering, except rain, and at present are very healthy and free from disease. Surplus fruit and vegetables are sold in Alawoona.

A very fine crop of 60 acres of Guyra oats, sown the third week in March with 35lbs. seed and 50lbs. super on stubble land, was inspected on Mr. H. J. Koch's holding. The crop is quite 5½ft. high, and is expected to cut 1½ to 2 tons of hay to the acre.

Mr. T. B. Flint, who took up land in 1914 when the district was first settled, has a holding of 1,882 acres—200 acres of which remain to be cleared. Sown to wheat this year he has 450 acres, and 120 acres of oats. His best crop was one of Nabawa, which should yield six bags to the acre. To provide adequate grazing for a flock of 200 Merino sheep, Mr. Flint has sown Wimmera rye grass all through his wheat crops, and in addition has a plot of 2½ acres of the grass, which he intends to harvest for seed.

Perhaps the best and most attractive crop inspected was one of 70 acres of Nabawa wheat on the farm of Mr. A. Bishop, who, before taking up wheat growing, was a gardener at Mount Compass. This crop, which was sown with 45lbs. seed and 70lbs. super in mid-April, was at the time of inspection clean, level, and very dense, and gives every appearance of returning 8 bags to the acre. He has 400 acres under wheat this year, and proposes to make adequate provision for fodder supplies by cutting 60 tons of Golden Drop wheat for hay.

Mr. W. Paull, who is Chairman of the local Branch of the Bureau, and last year won the District Crop Competition, works—in conjunction with his son—two properties, containing 3,500 acres. On this holding very fine crops of Caliph and Gallipoli and Nabawa were inspected. Realising that as a general rule the mallee lands will not stand consistent cropping, Mr. Paull practices a rotation whereby the paddocks only come under wheat once in five years. He expressed the opinion that right through the mallee many farmers put in too large an area. This they cannot handle properly. In proportion to the size of his holding, Mr. Paull said he put in a smaller area of wheat than anyone in the district, and at the same time there were few who marketed more wheat than him. Provided a good finishing rain is received, Mr. Paull anticipates a yield of 30bush. to the acre from a paddock of 115 acres of Nabawa. Mrs. Paull was complimented on her very fine flower garden, which was a blaze of color at the time of the inspection. Visitors were entertained at lunch and tea by the ladies of the district, and a most instructive and enjoyable day concluded by a concert in the Institute.

SOUTH AND HILLS DISTRICT

BELVIDERE.

May 21st.—Present: 11 members.

Horses *v.* Tractors.—The Hon. Secretary (Mr. M. Pearce) read the following paper:—"Tractors are heavily handicapped by their high initial cost and unknown costs for repairs and upkeep. Petrol, oil, &c., imported from abroad is paid for in cash or goods; whilst horse feed is grown on the farm with little more than the farmer's own labor." The speaker thought that if a farmer wanted to work a tractor it would be essential to have a large area and keep the tractor going day and night to get the crop in at the most opportune time in the season and thereby possibly increase the yield. He also thought that the only other occasion a tractor may be used economically was when horse feed could not be grown; as in clearing new country. Several members thought a tractor would be a benefit to help the horse team in the busy times. Mr. Watson said that a light tractor could be used on a small dairy farm because it would allow feed to be given to cows which would otherwise be eaten by horses. Mr. E. Sparrow cited the case of a tractor in the Bordertown district which, working in shifts, put in 700 acres in 12 days, including cultivating, drilling, and harrowing. The general opinion of members was that horses were the best for farm power.

A meeting was held on June 16th, there being present 15 members. Mr. R. Hill (District Agricultural Instructor) delivered an address, "Seeding Operations."

CROWN LANDS.

LANDS OPEN TO APPLICATION.

Applications will be received until 3 p.m. on Tuesday, October 18th, 1932, for lands in the Hundreds of BARNA, BLACKER, BOOTHBY, BROOKER, BUCKLEBOO, BURGOYNE, CAMPOONA, CARALUE, CARAWA, CARINA, COLTON, COOTRA, CUNGENA, FINLAYSON, GOODE, HAGUE, HASLAM, KIANA, KOONGAWA, LAKE WANGARY, MAMBLIN, MANGALO, McLACHLAN, MILTALIE, MINBRIE, MINNIPA, MITCHELL, MOODY, MOORKITABIE, MORTLOCK, MOSELEY, PYGERY, ROUNSEVELL, SHANNON, SMEATON, SOLOMON, STURDEE, ULYERRA, VERRAN, WANNAMANA, WRENFORDSLEY, YADNARIE, and in the Counties DUFFERIN, KINTORE, and ROBINSON.

Full particulars are published in the *Government Gazette* of September 8th, 1932, and plans and detail may be obtained on application to the Director of Lands, Box 293A, G.P.O., Adelaide.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

R. S. Richards, Commissioner of Crown Lands.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Australian Wine—Growing Use in the United Kingdom.

The great increase in the export of Australian wine to the United Kingdom is mentioned in the Report on Wine which has been issued by the Imperial Economic Committee (H.M. Stationery Office, 6d.). Australian wine is firmly established and the consumption of it in the United Kingdom has been increasing during the last three years, although the general consumption of wine has declined. Australia itself, says the Report, consumes just over 6 pints a head, where South Africa consumes 15 pints. The United Kingdom consumes just over 2 pints of wine a head. Australian exports were greatly stimulated by the export bounty, which, at varying rates, has been in force since 1924, and increased fivefold, to two and a half million gallons, in six years. This is about half the estimated quantity consumed in Australia itself.

The report gives the world's total annual production of wine at around 400,000,000 gallons, half of which two countries, France and Italy, provide. The British Empire only provides 1.31 per cent. of the total.

UNITED KINGDOM MARKET.

In a careful study of the United Kingdom market, it is estimated that the average amount of wine drunk annually per head of the population is some 2½ pints. Consumption has been practically constant since 1886. There has been a certain change of taste towards sweet and away from dry wines, and it is in providing good sweet wines that Empire growers have a particularly favorable field. The steady consumption of wine, although the duties were doubled in 1920, is in part due to the increased taxation on beer and spirits. Taxation and preference play a great part in changing public taste, as the classic example of port wine shows, and under the new Imperial preferences Empire growers have an excellent opportunity.

RECOMMENDATIONS TO EMPIRE GROWERS.

The Report recommends growers to seek to put on the British market a few aristocrats among wines, whose undisputed excellence will confer prestige upon the land from which they come. Mr. H. Warner Allen, a recognised authority, is quoted in praise of South African sparkling wine, dry Dominion, and of distinctinve Australian wines. These wines have qualities of their own, but they have to make their way in a market whose taste is already trained by the wines of Europe. Just as the wines of France, Germany, Spain, and Italy are all quite different, and are not compared against each other, so should the Empire wines win their own niche.

Great efforts are now being made to improve quality, and it is recognised that much harm was done by the premature export of inferior wines some years ago. In hotels and restaurants, in particular, the goodwill of the management is of little effect where consumers choose the foreign label "either through fear of venturing on the unknown or on evidence of their supposed knowledge." The report points out that organisers of public and official dinners, old boys gatherings and similar functions have a great chance of giving prominence to Empire wines worthy of serious consideration.

BLENDED WINES.

Empire growers have to face the competition of blended European wines, which are blended not for improvement, but simply to obtain a wine on which the duty works out at nearly the same as the duty paid by Empire wines. The practice of adding spirit to Empire wines in bond to obtain alcoholic strength is one which injures the name of Empire wines.

NAMES FOR WINES.

Such names as Burgundy and Claret have for long been used to describe types of wines and not particular localities. Australian Burgundy, for example, has been on the market for over sixty years. But Port and Madeira are words whose use is restricted by law to certain localities. Port constitutes over a quarter of all the wine imported into Great Britain, and the Portuguese enjoy a very great advantage. Empire producers of wine of port character have added such words as Port Type, but there are great disadvantages in this practice, which suggest an imitation. It follows that very careful consideration should be devoted to the possibility of inventing new names for Empire sweet wines. "Austral" or "Aust" have been proposed for Australian sweet wine, or the revival of old names like Malmsey. In general the Report pleads for an acceptance of the view that the usual names for Wines have become general in meaning and ought not to be limited to particular countries.

NEED FOR LARGER EXPORTS.

The two great Wine producing countries in the Empire are Australia and South Africa, although Canada, Cyprus, Malta, and Palestine all produce Wine, and there is British Wine—elderberry, cowslip, ginger, &c. Australia consumes less than a third of her own production of around 18,000,000galls., while South Africa, whose total production is about 19,000,000galls., only exports between 4 per cent. and 5 per cent. of it. Australia exports more than twice as much as South Africa, and both countries send over 90 per cent. of their exports to the United Kingdom. But total sales have not kept pace with production. Larger export markets, alike for Wine and Brandy, are the chief need of both countries. Markets in Empire countries, other than the United Kingdom, deserve attention, though few of these countries at present give tariff preferences to Empire Wines.

BRANDY.

The increased sale of brandy indicates a way in which Empire producers can extend their markets. South Africa is a particularly large consumer, and annual consumption per head is 12 times what it is in the United Kingdom. Australia consumes five times, Canada three times as much per head as the United Kingdom, where consumption has been decreasing for many years and is now only half a million proof gallons. Empire brandies have to compete in a narrowing market with established foreign brandies. France, in fact, enjoys a monopoly, and the public relies on the names of a very few well-known shippers of French brandies.

Empire brandy thus finds it difficult to obtain the recognition its high quality deserves, and is only ½ per cent. of all the brandy consumed.

The laws of Australia and South Africa are strictly administered and guarantee that brandy is properly manufactured from wine and properly aged. South African brandy has been used by the London County Hospitals as their sole brandy for the last five years, and is in use in more than 400 hospitals in the United Kingdom. If producers can produce in time a few liquor brandies of the highest type it will greatly help to establish Empire brandies.

Fertiliser for Maize.

The Myponga Agricultural Bureau asks "What is the most suitable manure for a crop of maize growing on swampy land"? Mr. W. J. Spafford (Deputy Director of Agriculture), in reply, says maize grows really well on peaty soils, provided the crop receives sufficient mineral manures. To ensure a really heavy forage crop of maize, about 3cwts. superphosphate per acre should be drilled in with the seed. If the crop is to be grown for grain, from 2cwts. to 3cwts. superphosphate and ½cwt. to 1cwt. muriate of potash should be applied per acre. More important than manure, however, is the necessity to grow the maize in rows, and keep the land between the rows well cultivated while the plants are small enough to permit of cultivation.

World Economic Survey, 1931-32.—This publication, issued by the League of Nations, gives a review of the development of the world depression up to the middle of July, 1932. Illustrations of economic developments are drawn from different countries or group of countries, but the description throughout is of world problems. Special references are made to the disorganisation of production, prices, and trade, the growth of unemployment, and public finances. Australian agents: H. A. Goddard Limited, 255a, George Street, Sydney.

HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. Geo. Quinn, Chief Horticultural Instructor.]

Orange Trees Shedding Young Fruits.

Kimba Agricultural Bureau. "What is the cause of orange trees shedding young fruits"? Reply—It is suggested that the trunk of the tree be cinctured when the blossoms are just falling freely. This consists of selecting a smooth, round place on the trunk, and with a sharp knife making a clean cut right around the trunk, pressing the knife edge through the bark until the resistance of the wood is freely felt. If the tree is very vigorous, make a second cut about 6in. or more above or below the first. Do not try to lift the bark or take out a strip, but make a plain, clean, straight cut right around the stem.

Preventing Ants Ascending Fig Trees.

Appila Agricultural Bureau. "What is the best treatment to prevent ants ascending a fig tree and spoiling the fruit"? Reply—Fix a rubber or tough, grease-proof paper band about 6in. wide around a smooth part of the stem and keep it smeared with a mixture of tar and just sufficient oil or grease to prevent the tar drying off and losing its stickiness. Any kind of sticky band will do, but do not allow any oily or tar mixture to run down on to the bark of the trree.

Making a Plum Tree Fruit.

If the tree is a variety which is known to set fruit in other gardens without the presence of another plum which blooms at the same time, then the cause of non-fruiting may be due to some cultural defect. Usually, such trees, if healthy and vigorous, are more likely to flower and set fruits if left unpruned for a season or two. Driving nails into the trunk may give a check to the sap flow, but if that is necessary, probably cincturing by running a knife cut around the trunk when the blossoms are fully expanded would probably act more directly. If the tree flowers freely, and never holds its fruits, it probably bears self sterile blossoms, and needs the presence of another plum which blooms simultaneously with it. This can be tested by placing flowering twigs (if obtainable) from another kind in tins of water, and hanging them up amongst the flowers of your own tree. The bees and insects will effect the necessary cross pollination.

Preventing White Ants Attacking Fruit Trees.

No reliable and non-injurious preventive is known which can be inserted into the trunk, but white ants could be attracted and poisoned by soaking the lower half of pine or stringybark stakes in a solution of arsenic and driving them into the ground around the tree stem. White arsenic may be dissolved by boiling it with about twice its own weight of washing soda, or by treatment with equal quantities of caustic soda in a small volume of water.

VETERINARY INQUIRIES.

[*Replies supplied by Veterinary Officers of the Stock and Brands Department.*]

"Tweedvale".—What is the value of saltpetre, treacle, and ginger as a preventive for mammitis, given before calving.

Reply—Mammitis (inflammation of the udder) is due to the entrance of germs into the udder, and there is no medicine which will prevent the disease, and the only effect of giving these ingredients would be to increase the action of the kidneys and help to keep the bowels in a laxative condition. The best preventive for mammitis is to keep the animal in a healthy condition by good feeding and under cleanly conditions, and if any drench is required to keep the bowels active, give Epsom salts 1lb. to 1½lbs., with ginger 2ozs., treacle 1lb., and water 2 pints as one drench.

Secretary, Aguricultural Bureau, Palabie, reports cow which is eating horse manure.

Reply—This is an indication of a mineral deficiency in the food, and most probably the deficiency is phosphorus. This can be rectified by supplying any of the following mixtures:—(1) Di-calcic phosphate, 40 parts; common salt, 60 parts. Mix thoroughly, and in some bran and chaff give 1oz. for each gallon of milk produced per day. (2) Sweet bone meal, common salt, equal parts. Mix well. (3) Superphosphate, common salt, equal parts. Mix well. The quantity of Nos. (2) and (3) mixtures to be fed is the same as in feeding No. (1) mixture. Young growing animals should also have free access to any of the above mixtures, which can be kept in a cut down kerosene tin sheltered from the weather. Di-calcic phosphate can only be purchased from the Crosco Co.

Secretary, Agricultural Bureau, Weavers, asks—"What is the best preventive for bot flies"?

Reply—There is no known effective remedy for preventing the fly from "striking" horses. To minimise as far as possible the chances of the animals becoming subsequently infested with the larvae, the eggs, after they have been deposited on the hairs of the coat, can be destroyed by singeing or by smearing with raw linseed oil 2 parts, kerosene 1 part.

NO BREAKDOWNS

during harvesting, because

Mobiloil stands up

YOU can't afford any risk of tractor breakdown during harvesting. That is one reason why you should use Mobiloil. You want to get your harvesting done as quickly as possible—that's another. Still another reason is the need for the greatest economy. Mobiloil will give you that.

Mobiloil is made to stand up to the hardest work, and it will enable your tractor to stand up to it, too.

. . . and for money-saving Extra Power use

VOCO POWER KEROSENE

VACUUM OIL COMPANY PTY. LTD.

"Paruna" reports mare stiff in all four legs following difficulty in foaling four weeks previously.

Reply—The symptoms are those of inflammation of the sensitive structures of the feet (laminitis), which is not an uncommon condition, and in this case is probably a complication following inflammation of the womb. *Treatment.*—If possible place the mare in a shallow foot bath made by digging a trench and filling with water sufficient to cover the feet as high as the fetlocks. Before placing the mare in the bath and filling with water, the bottom of the bath should be covered with chaffed straw in order to prevent the suction of wet clay on the feet. Keep the mare in the bath all day, and remove her into a stall well bedded with straw. The heels of the feet should be rasped down in order that the weight is taken off the front of feet. If constipated, give 1½ pints of raw linseed oil as one drench. Feed on green feed, bran, and a little boiled grain. In the latter can be mixed 2 tablespoonsful of baking soda twice a day.

"Mount Cooper" asks if a bull is likely to be injured if allowed to serve cows at 12 months old.

Reply—It is recommended that bulls be used only to a limited extent from 15 months to 2 years. If the bull is used only occasionally no ill effects will occur.

"Wepowie" asks the probable cause of a mare carrying a dead foal.

Reply—1. A serious fall may lead to the death of the foetus, in which case abortion usually occurs. In the case you mention the period between the fall and the taking away of the foetus was probably too long for the accident to be connected with the death of the foetus. 2. Abortion in the mare may be caused by—(1) A serious illness, *e.g.*, colic; (2) severe and excessive work, especially if mare is unused to it; (3) accidents, *e.g.*, kicks, falls; (4) many mares abort the 12th week of pregnancy, as attachment to foetus to breeding bag is very weak at this time; (5) disease of the uterus; (6) contagious abortion rarely occurs in mares. 3. The abundance of early green feed would not cause abortion, unless the feeding of it gave rise to colic or laminitis, *e.g.*, horses are frequently put on to green crops and the sudden change and excess of feed often leads to an attack of founder, which in a pregnant mare may cause abortion. 4. Duration of pregnancy in mare is on an average 48 weeks (from 305 to 400 days).

Secretary, Agricultural Bureau, Frayville, asks the cause of horses stamping their feet and rubbing against fences.

Reply—The probable cause is the presence of a small parasite in the hair of the legs below the knees and hocks. The treatment indicated is the application of the following dressing two or three times, at intervals of 4 to 5 days:—Take raw linseed oil or any vegetable oil 1 pint, lysol 4 tablespoonsful. Shake thoroughly before applying with a brush to affected legs, rubbing the mixture in.

SALT IN WATER.

[*Quantity Tolerated by Horses, Cattle, and Sheep.*]

Mr. R. H. F. Macindoe, B.V.Sc., M.R.C.V.S. (Deputy Chief Inspector of Stock), advises the Secretary of the Milang Branch of the Agricultural Bureau, who sought information on the above subject, that—(1) Horses will thrive on water containing 400 grains common salt and 550 grains total solids per gallon, and, provided they are not worked, may be sustained on water containing up to 638 grains salt and 950 grains total solids. Water containing as much as 798 grains salt and 1,022 grains total solids has been used for a period of three months without ill effects. (2) That cattle will thrive on water containing 800 grains common salt and 1,000 grains total solids, but when the concentration reaches 970 grains salt and 1,300 grains total solids they are injuriously affected. (3) That sheep will thrive on water containing 800 grains common salt and 1,000 grains total solids, and will do well even up to 1,197 grains salt and 1,350 grains total solids. When the concentration reaches 1,277 grains common salt and 1,868 grains total solids the sheep are injuriously affected.

Ford 30-cwt. Stakeside Truck (131½″ wheelbase) with enclosed cab and special malleable steel wheels—dual at rear.

STRONGER and MORE POWERFUL is this improved 30-cwt. Ford Truck . . . .

RUGGED strength and an unusual capacity for heavy work have always been characteristics of the Ford 30-cwt. Truck. Yet both strength and performance have now been notably improved.

Performance . . . The New 4-speed Gear Box (with Power Take-off) gives higher road speeds and tremendous pulling power for soft ground or excavations . . . 5 ball and roller bearings reduce friction . . . In all forward speeds, the entire drive (from engine to wheels) is on ball or roller bearings . . . A Power Take-off is provided for tipping or for belt-work operations.

Strength . . . The stronger Front Cross Member and heavier new 2¼″ Front Spring provide a greatly strengthened front suspension, capable of withstanding hard driving at speed with capacity loads over roughest tracks. Radiator, engine, clutch and transmission are relieved from all road strains.

SOME POINTS IN THE HANDLING OF A FAT LAMB FLOCK ON A MALLEE FARM.

[By ARTHUR J. PERKINS, Director of Agriculture.]

(*Paper read at the Forty-third Congress of the Agricultural Bureau, September,* 1932.)

1. INTRODUCTORY.

The title of my address commits me to the discussion of the position of Sheep on a Mallee Farm; and whilst I shall try to do justice to this commitment, my main aim tonight will be to use it in such a manner as to stress not merely the advantages, but in existing economic conditions the imperative necessity of associating Live Stock operations—Sheep, Dairy Cattle, Pigs, Poultry—with Wheat in whatever part of the State the latter may be grown, and perhaps I should add of the Commonwealth as well. I need scarcely remind you that within recent years rural producers generally have had to face an unprecedently low scale of prices for their products coming in quick succession to post-war inflation; and that this phenomenon, which might have been foreseen, but was not, has led to painful economic readjustments throughout the community. Rural producers have suffered in common with others, but let us not forget that the chief sufferers have been those who are still tramping the streets of our cities in search of work. It is probably true that on a strict accountancy basis neither Wheat Farming, Sheep Farming, Dairy Farming, Poultry Farming, &c., taken singly, is a paying proposition at prices current to-day; but it does not follow that a judicious combination of two or more of these lines of rural activity should not suffice to help individual farmers to retain a firm grip of their holdings until such time as general world economic settlement leads to a return of more normal prices. If this be granted, the present day ideal farm would appear to me to be a farm as nearly as possible self-sufficing, purchasing a bare minimum of outside necessaries, bringing to market a maximum of saleable commodities, and providing throughout the year continuous employment for the farmer and his family. If the outlet for the farmer's saleable commodities were strictly confined to a limited home market, it is obvious that the general adoption of a policy of this kind would ultimately prove suicidal; fortunately, however, the commodities we have in mind—Wheat, Wool, Fat Lambs, Barley, Butter, Cheese, Frozen Pork, Eggs, &c.—all have recognised over-seas values which, although undesirably low at the present moment, are not altogether prohibitive when expressed in terms of a high adverse exchange rate. I realise one difficulty, indeed an insuperable difficulty for some settlers, namely, reasonable over-seas marketing facilities: its discussion would, however, involve me in matters of State policy, which are outside my province; and I must leave its solution to the powers that be.

It has always seemed to me that in any country, but particularly so in a country dependent upon rural production for its very existence, land ownership was in the nature of a trusteeship, with moral obligations that no owner could afford to overlook, namely, that broad acres should be exploited not merely for the private advantage of the occupier, but in addition for that of the community as a whole: and if this be granted, no cleared farm that brought nothing more than Wheat to market could be said even in the best of circumstances to be adequately filling the requisite functions of a farm, but particularly not so in existing economic conditions. From the bare standard of Labor requirements alone, can it be seriously maintained that Wheat affords scope for continuous employment from one end of the year to the other? As to associated economic disadvantages of this single crop I shall have occasion to refer to them at a later stage.

It is my firm conviction that the future success of Wheatgrowers throughout the Commonwealth is dependent very largely upon the extent to which they are able to adjust themselves to the association of Wheat with Live Stock operations: and, if in the sequel I confine my remarks to Sheep in support of this conviction, it will not be because I underrate the value of Cattle, Pigs, or Poultry in the same connection. Indeed, if I were asked off-hand what type of Live Stock I would in present circumstances recommend for a Wheat grower of limited means and credit, I should unhesitatingly recommend Dairy Cattle as a first instalment: and I find it difficult to believe that any kind of farm—be it a wheat farm, a dairy farm or even a fruit farm—can afford to be without its flock of hens. If, therefore, I confine my remarks to Sheep it is because my colleagues—Messrs. Barlow and Anderson—will deal very adequately with Dairying and Poultry tomorow evening.

It remains for me to justify my selection of the Mallee for purposes of illustration in preference to the State as a whole. My reasons may be stated as follows:—

a. I happen to have precise data on the subject from a Mallee farm, which are essential to my arguments.

b. For a variety of reasons Live Stock operations on Wheat Farms have hitherto been neglected to a greater extent in the Mallee than elsewhere in the State.

c. And yet for both technical and economic reasons the presence of Live Stock on Mallee Farms is more essential to the success of wheat growing than elsewhere in the State.

d. And finally, from the arable standpoint, South Australia is a Mallee State to a far greater extent than is usually suspected.

My last reason is supported by the following facts: Latest Statistics—1930/31—give 15,602,000 acres as the total area available for cultivation in South Australia: of this area I calculate 10,199,000 acres, or close on two-thirds to be in Mallee country: similarly, in 1930/31 the area under Wheat in South Australia was 4,181,000 acres, of which 2,940,000 acres, or over 70 per cent., were in Mallee country; the area under Bare Fallow, 2,495,000 acres in South Australia, and 1,349,000 acres, or 54 per cent. in Mallee country; the area under Oats and Barley 470,000 acres in South Australia, and 335,000 acres, or 71 per cent., in Mallee country; and, finally, the area under all other crops 775,000 acres in South Australia and 376,000 acres, or 49 per cent. in Mallee country. These data should suffice to stress the importance of Mallee country in South Australia.

If we take into consideration the fact that Mallee country cannot be brought under Wheat to advantage more frequently than once in every three or four years, we may note incidentally that the maximum area under Wheat that the State is normally capable of carrying in any one year is not likely to exceed 4½ million acres.

But, if Mallee country cannot carry Wheat to advantage more frequently than once in every three or four years what is to be done with the land in intervening years? Is it to lie idle and recuperate, and provide grazing grounds for a few working horses—and not even that if tractors are to supply requisite motive power? In such circumstances it will be easy to prove how onerous wheat growing is likely to prove even at prices very much in excess of those that have obtained within recent times.

2. THE IMPERATIVE ECONOMIC FACTOR BEHIND LIVE STOCK ON THE WHEAT FARM.

Quite recently I have had the advantage of analysing the Accounts—1929/31—of a Murray Mallee Farm, on which Wheat growing has been combined with Sheep to the exclusion of all other types of Live Stock. The farm in question is 1,685 acres in area, with an available arable area of 1,655 acres. The mean area sown

to Wheat has been 439 acres, from which an average of 14.78 Bushels to the acre has been reaped. This mean yield per acre must be accepted as good, since over the same period—1929/31—the mean yield per acre in the Murray Mallee Division was 6.03 Bushels only, in the combined Mallee districts of the State 6.37 Bushels and in the State as a whole 7.44 Bushels. The mean area fallowed has been 510 acres and about 100 acres of Oats have been reaped annually for grain, the greater portion of which has been used as seed for grazing crops of Oats to which Sheep and Working Horses have had regular access.

Inclusive mean costs of growing wheat have been as follows:—

	Costs per Bushel. s.	d.
Interest on Land and Improvements	0	4
Interest on Working Capital	0	3
Depreciation on Improvements and Plant	0	9
Rates and Taxes	0	0¼
General Expenses	0	2
Labor	0	7
All other Costs	1	4
Mean Inclusive Costs per Bushel	3	5

In the above statement, in which mean inclusive Costs per Bushel of growing Wheat have been shown to be 3/5, details have been so arranged as to give prominence to those special charges which are so often overlooked in the determination of Costs by Amateurs: if, for instance, the first five items were to be omitted, it could be said with some show of reason that the Wheat costs 1/11 a Bushel only, instead of 3/5; and that even at present prices the owner must have realised quite handsome profits on his Wheat crops. Actually, notwithstanding the owner's recognised ability as a farmer, the Wheat Account closed at a loss of £171 7s. 3d. in 1929-30 and of £529 17s. 1d. in 1930-31.

The point I wish to make, however, is that if Sheep had not been present on the farm to turn to some advantage large areas of land lying temporarily idle, and to take up their share of these special over-head charges, the cost of growing Wheat, instead of 3/5 a Bushel, would have been considerably higher. Let us take a closer view of the position: the mean value of these overhead charges for the whole farm was as follows:—

	£	s.	d.
Interest on Land and Improvements	336	11	11
Interest on Working Capital (excluding Sheep)	103	16	2
Depreciation on Improvements and Plant	404	14	7
Rates and Taxes	25	17	2
General Expenses	123	12	11
Value of Owner's Management and Labor	300	0	0

The above statement shows that mean overhead charges (including estimated value of the owner's Management and Labor) incurred by the farm as a whole averaged £1,294 12s. 9d. per annum. Out of this total £675 16s. 8d. only was debited against 439 acres of Wheat, which returned 6,488 Bushels at harvest time, that is to say, a charge of 2s. 1d. per Bushel: the balance, £618 16s. 1d., may be said to have been taken up by the Sheep Account, since the Oat crops were used almost exclusively by Sheep. Hence, if Sheep, or some other kind of revenue-earning Live Stock, had not occupied the idle grazing areas of the farm, wheat would have been the only revenue earning Account, and would in consequence have been debited with £1,294 12s. 9d. in the way of overhead charges, instead of £675 16s. 8d., with the result that the Wheat, instead of costing 3s. 5d. a bushel, would have cost 5s. 4d.

It follows, therefore, that when on a Wheat Farm we take up Live Stock operations, however much we may do so in the hope of securing direct profits from the venture, nevertheless, in view of the financial relief these operations give to main crops, the former can be taken to have succeeded economically even when they do no more than square the ledger. But one can go further and say that even if Live Stock operations were to show an apparent Loss for the year, so long as this Loss did not exceed the value of the overhead charges of which main crops had been relieved by Live Stock—£618 16s. 1d. in the case under consideration—the farmer would have been no worse off than if his farm had not carried a single hoof of Stock, apart from slightly increased interest charges.

From the above considerations it should be realised, I think, how wasteful from a community point of view is the policy of those who in country on which Wheat can be grown on the same plot of land at long intervals of time only, persist in excluding Live Stock from their farms, and how onerous on their own purses.

3. OTHER ADVANTAGES OF ASSOCIATING LIVE STOCK WITH WHEAT.

Such, then, is the main economic advantage of associating Live Stock operations with Wheat in the Mallee, and one can add over the greater portion of the State. But this, as you will know, is very far from being the only advantage that Farmers derive from this association, apart altogether from possibilities of direct profits. The facts are too well known to need any stressing and I shall content myself with their brief enumeration. In the first place, our unavoidable practice of making eight to nine months of well-tilled Bare fallow precede a crop of Wheat, has the effect of progressively depleting the normal stock of soil organic matter, so essential to its good mechanical condition and to the life functions of useful soil bacteria: depasturing Live Stock and Sheep in particular return to the soil quite appreciable quantities of organic matter in appropriate form. Sheep, too, assist to keep in check undesirable but edible weed growth, which if allowed to go to seed, would lead ultimately to a reduction in crop yields. The presence of Sheep on Bare Fallows is common, I know, and perhaps unavoidable: such a practice should not, however, be abused; it may be good for the fallows—it will certainly help to consolidate them, provided the land be neither over-steep nor over-light in texture—and it will probably lead to an apparent reduction in tillage costs: but "fallow-roaming" has its drawbacks even for the farmer's pocket: over indulgence in it is mainly responsible for "shabby" fleeces and low wool prices and is apt to develop muscle rather than market condition in Sheep. I realise, however, that on present-day farms Wheat is of greater economic importance than Sheep, and that within limits we cannot avoid fallow-grazing; but let us make no immoderate use of it.

4. TYPE OF FLOCK FOR THE AVERAGE FARM.

What type of Sheep is best adapted to Mallee conditions? I know that some argue for a quick turn-over fattening flock and others for a breeding flock; personally, I side with the latter, both from the State viewpoint and from that of the average farmer. It seems to me that farming as an occupation offers sufficient elements of chance to satisfy the gambling instincts of most men; hence, when a suitable alternative presents itself I suggest that the average man should beware of staking his Capital on market uncertainties. Markets have been known to drop unaccountably between purchase and sale time, and "fats" have sometimes realised less than their original value as "stores", to say nothing of those whose misfortune it is at times to buy "fats" and sell "stores"; possibly the latter put undue faith in fallow-grazing. The fact of the matter is that like the poet the successful dealer is born, and not made, and in my experience, I think we can add that like most poets, he is rarely a good farmer. In my opinion, therefore, the average man should pin his faith to a breeding Flock, and where economic conditions permit of it, to what is known as a Fat Lamb Flock; under careful management parturition losses should not as a rule exceed by much those common to casual grazing flocks; breeding Ewes, more at home on the farm, should prove quieter, and hence more thrifty; the danger of introducing undesirable parasites should be lessened; the flock should be at its maximum at that time of the year when grazing facilities are usually at their best and at its minimum when grazing is at its scarcest; and finally, fleeces and natural increase should under normal management ensure some return on Capital, however depressed prices may happen to be at the time.

5. The Fat Lamb Flock.

The breeding Flock, I have said, should be a Fat Lamb Flock whenever local conditions permit of it; by this I mean that if local marketing facilities were such that there was no possible outlet for Fat Lambs, then the farmer must fall back upon Merinos, or preferably perhaps extend his Dairy Herd to the full capacity of farm and family labor. In the matter of the constitution of a Fat Lamb Flock there has been a good deal of difference of opinion in the past, mainly because we have been groping our way through a period of transition in the course of which the influence of local buyers has hitherto proved more potent than that of over-seas markets. And unfortunately, in a matter of this kind local influence makes for chaos, since the local market will accept any type of Lamb that is market prime, and frequently pay more for it than is obtainable at the time for better class stuff on an export parity. Over-seas markets, on the other hand—mainly British ports—are catered for by a number of countries, and are able to pick and choose in the matter of quality nor can we expect to command the most satisfactory prices until we conform to over-seas requirements, as had been done for many years past by New Zealand, and more recently to some extent by Victoria. The British Market requires a sturdy, well built, but not over-fat Lamb, dressing not more than 30lbs., and preferably under; with dark face and points and high quality flesh, free from the tallowiness characteristic of some breeds. At the present time it would be exceedingly difficult to get an even line of Lambs of this type in South Australia, simply because breeders are keeping their eyes fixed upon the local market, and not upon overseas ports. In 1930 we slaughtered 368,531 Lambs of which 20,789 or 5.64 per cent. only were exported: in 1931 total slaughterings rose to 491,403 head, of which 135,386 or 27.55 per cent. were exported. Progress achieved has therefore been quite satisfactory, and if it can be maintained at the same rate, Lambs slaughtered for export will soon exceed those retained for home consumption: and when this is brought about the export trade will impose its standards and parity prices on the local market, and our Flocks and Lambs, much to the advantage of growers and the Commonwealth, will gradually tend towards uniform standards of quality. In the meanwhile, we can do little more than set up an ideal, and individually aim to reach as near as possible to it.

6. Suitable Dams for Fat Lambs.

The quality and type of the Lamb will be affected by the inherited tendencies of both Sire and Dam and by the extent to which environmental conditions enable it rapidly to reach market ripeness. The ideal Dam for the purpose would from this point of view be one of the long wool British breeds available in Australia—Lincolns, Border-Leicester, English Leicester, or Romney-Marsh: but the farmer has to consider more than quality in the Lamb, namely, the full value of Flock revenues, of which the Dam's Fleece forms an important part: hence pure-bred Long Wools must be discarded as suitable Dams for Fat Lambs in the Commonwealth, because of relatively unprofitable fleeces, usual non-availability in the commercial sense, and in many cases because of incomplete adaptability to local conditions. From the standpoint of export quality in the Lamb, we must place in second line Half-bred Long Wool Dams—Merino x Lincolns, Merino x Border-Leicesters, Merino x English-Leicesters, and Merino x Romney Marsh—with which can reasonably be included Corriedales, if commercially available. All Ewes of the above type should make admirable dams for Fat Lambs: all are reasonably prolific and less liable to parturition difficulties than Merinos in lamb to Rams of British Breeds; they are good mothers, well able to protect their offspring and to nurture them rapidly to market ripeness; they will carry Lambs readily as two-tooths; and, finally, when their period of usefulness as dams has been completed, they will fatten off without difficulty.

The value of the Fleeces of these half-bred Ewes relatively to those of Merinos must necessarily vary with market demands at the time of sale: but, in the vast majority of cases, Merino wool, not excluding "shabby" farm wool, has on a per-pound basis had the advantage over cross-bred wool. From the viewpoint of "fleece values," however, weight of fleece is as important as value per pound: and in the latter connection, whilst Merino Ewes are frequently found carrying even heavier fleeces than average cross-bred Ewes, the strain of adequately rearing a lusty half-bred Lamb tells heavily on the fleece weight of the Merino Ewe, with the result that not infrequently a half-bred Ewe mothering twins will yield a heavier fleece than a Merino Ewe suckling a single half-bred Lamb.

The relationship of Fleece values was among other things worked out in detail by Messrs. Colebatch and Scott in their admirable report on Fat Lamb tests conducted at the Roseworthy Agricultural College (1924-26)*: figures given below show some of their findings on the subject, together with corresponding figures for present-day prices:—

	Mean	Values—					
	Fleece	Per Lb.		Total.			
	Weights.	1924-26.	1931.	1924-26		1931.	
	lbs.	d.	d.	s.	d.	s.	d.
Merino	11	18.55	8.45	17	0	7	9
Merino x Lincoln	12	14.67	6.92	14	8	6	11
Merino x English-Leicester ..	10½	16.38	7.43	14	4	6	6
Merino x Border-Leicester ..	10¾	15.72	7.26	14	1	6	6
Merino x Romney-Marsh . ..	11	15.55	7.18	14	3	6	7

Fleece values shown for 1924-26 may possibly make sheep-breeders' mouths water; but, coming down to present-day hard realities, the difference between these Roseworthy Merino and Cross-bred Fleeces respectively would on present-day values have varied between 9d. and 1s. 3d. per Ewe in favor of the Merino, a difference which the normal sale of Fat Lambs of higher grade would readily have made good. Nor should the fact be overlooked that data given are those of a small, carefully tended Flock under experimental test, and that under average farm conditions it is by no means certain that Merinos would be able to retain to an equal degree their apparent fleece value superiority: when times are hard cross-breds are the better foragers.

From these various considerations it can, I think, be safely accepted that a well managed Flock of half-bred Ewes should under existing local conditions not only give our nearest approach to the ideal export lamb, but in addition should on the balance return to the farmer the highest gross Flock Revenue that the times admitted. But, notwithstanding these outstanding advantages, there is one important fact which in existing circumstances does definitely preclude the general use of Ewes of this type on Australian Farms, namely, the usual impossibility of securing them when wanted, in adequate numbers and at right prices. It is true that it is sometimes stated that when such is the case farmers should breed their own Cross-bred Ewes: and whilst in special circumstances this could no doubt be done, for everyday purposes there are serious technical and economic objections

---

*See Journal *of Agriculture,* 1927 (September, October, November, and December numbers), "An investigation into certain aspects of Fat Lamb Production on Agricultural Holdings," by W. J. Colebatch and R. C. Scott.

to the practice. The main objection is probably the fact that to rear Cross-bred Ewes on a farm, when the ultimate economic objective was the sale of Fat Lambs, would render unavoidable the simultaneous presence on the Farm of small groups of Sheep of various grades, and this on the average farm would only lead to confusion and pecuniary loss.

In order to illustrate the position I shall take the concrete case of a farm able normally to carry 500 Breeding Ewes throughout the year with the help of a certain amount of hand-feeding over Autumn and early Winter. Such a farm would require about 200 Merino Ewes, which would be purchased according to needs, in order to supply sufficient Ewe Lambs by a Long Wool Ram to provide for the regular renewal of the Cross-bred Flock every fourth year: allowing for normal casualties, say about 85 Lambs per annum. Corresponding wether Lambs would not be ideal freezers and would probably be marketed locally.

The 300 Cross-bred Ewes would include 85 Maidens, which would not drop Lambs until the following season: this would represent a loss in revenue to the farmer which would not be balanced by the slightly improved value of their Fleeces.

In addition, such a Farm would have to carry five to six Long Wool and five to six Short Wool Rams.

From the Revenue standpoint the net result would be as follows:—Instead of a single line of Wool, of useful size from a sale's viewpoint, there would be three undesirably small lots of Merino, Cross-bred, and Cross-bred Lamb's Wool: and instead of a possible 425 Lambs of a freezer type there would be 85 half-bred Long Wool Wether Lambs and 183 Short Wool freezers.

Apart from these normal economic disadvantages, I am of the opinion that the multiplicity of grades can lead only to confusion and additional loss on the average farm, which as a rule does not provide facilities for the handling of more than one grade of Sheep at a time. It follows, therefore, that for the time being at all events, notwithstanding some obvious disadvantages, we shall have to content ourselves with Merino Ewes as Dams to the Fat Lambs of our average farms: and for the purpose none are better than the large frame, plain bodied Northern Merinos, in any district to which they can accommodate themselves.

The advantages and disadvantages of Merinos as Dams to Fat Lambs respectively may be summarised briefly as follows:—

Their main advantage is that as essentially the Sheep of the country they are usually available in almost unlimited numbers when required. They have readily ascertainable market values, nor, apart from temporary or exceptional circumstances, such as the breaking up of a period of drought, is there any call to pay fancy prices for them. Under careful management they may be counted upon for fleece-values at least as great, and generally greater, than those of any other Breed or Cross. They are hardy under our special conditions of climate, and will find themselves at home in almost any district, but particularly so in Mallee districts, except in localities in which underfoot conditions are exceptionally wet. And, finally, they are usually conscientious respectors of even moderately Sheep-proof fences.

Their natural timidity, particularly if Station-bred, which makes them nervous, wary feeders under the comparatively boisterous conditions of a farm, may be accounted one of their disadvantages which, however, gentle handling should overcome in the course of a season. In comparison with that of British Breeds and their Crosses, the fertility of Merinos is relatively low: they rarely carry twins, but when they happen to do so, both in the interest of the Dam's Fleece and the Fat Lamb, it is desirable to destroy one of the Lambs, or else to foster it upon a Ewe that had lost her lamb. Merino Ewes are not usually good mothers, both in the sense of a frequently inadequate milk supply and of that of relative carelessness of their young: when herded in large flocks, or unduly harried, they frequently lose their Lambs in the early weeks of the life of the latter. Finally, when their period of usefulness as breeders has been completed, they do not fatten off as readily as cross-breds, nor when occasion arises for it do they prove as amenable to hand-feeding as the latter.

Such as they are, however, we have no alternative at present but to accept Merinos as Dams to farm-bred Fat Lambs: and it may be added that when suitably mated and adequately tended they are quite able to rear satisfactory Export Lambs.

When purchasing Merino Ewes for farm purposes, six-tooths which should yield at least two crops of Lambs will probably prove the most profitable. Maiden four-tooths should generally be avoided because of parturition difficulties when mated with Rams of British Breeds. Two-tooth Ewes are undesirable for the same reason, and in addition because unless dropped early in the year, say February, and able to make strong development before wet, cold conditions set in, Merinos will carry Lambs at this age only exceptionally. Sound, full-mouth Ewes can also be acquired, on the understanding, however, that only those with sound mouths at shearing time should be retained for a second lambing.

7. Appropriate Rams for Fat Lamb Flocks.

From the standpoint of Export type the utmost importance that attaches to an appropriate choice of Sires for Fat Lamb Flocks, and particularly so when the Dams are Merinos, cannot be too strongly stressed. In this connection there are three special characteristics which we expect the Fat Lamb Sire to impress upon his progeny, namely, (1) early maturity, (2) good bodily conformation, and (3) high quality flesh: and it follows that not only must these characteristics be highly developed in the Sires used, but in addition the latter should belong to Breeds noted for a high degree of prepotency in these special characteristics, that is to say, the power of stamping them upon their progeny, notwithstanding opposing tendencies on the part of the Dams. Prepotency in pure Breeds of Live Stock is usually the result of careful breeding along definite lines, extending over a large number of generations, assisted at times by the judicious use of in-breeding: hence, subject to the above considerations, the older a pure Breed of Live Stock, the greater its power of transmitting intact within the Breed its racial characteristics, and of imposing them to a large degree upon crosses with other Breeds. The Merino—one of the oldest Pure Breeds of Sheep in the World—is correspondingly prepotent, but only in the matter of fleece upon which the attention of Breeders has been concentrated for centuries: carcass development, on the other hand—so essential a point in the ideal Export Lamb—has been for the most part overlooked in the Merino except to the extent of making adequate provision of a surface upon which fine Wool could be suitably grown. Hence, from the standpoint of Meat production the Merino carcass may be said to be highly defective: it is relatively long, narrow, flat-ribbed, high in the withers, very irregular in top and bottom outline, with poorly developed legs of mutton and coarse bone: the characteristic carcass of one who has had to wander far and wide for a living. In addition, the Merino is a typical natural, or late-maturing Breed. It must be obvious, therefore, that if from Merino Ewes we are to produce early maturing shapely Fat Lambs, the Sires used must be highly prepotent in these special qualities. And for the purpose no more suitable Rams could be found than well-bred Southdowns: they belong to the oldest, and therefore the most prepotent, of British Down Breeds, to which indeed the later developed Down Breeds owe their more recent improvement by early crosses. From our point of view Southdowns present the additional advantage of being on the small side, and as such, leading to a minimum of parturition troubles, which are common when Merinos are mated with the larger British Breeds. The smaller size of the Cross-bred Southdown Lamb is an additional advantage from the standpoint of present-day requirements of British Markets. Nor should it be forgotten that the World-famed Canterbury Lambs are for the most part sired by Southdown Rams.

But unfortunately the number of Southdown Studs in Australia is limited, and their combined output is very far below the requirements of Australian Fat Lamb raisers, present and future. Hence, when Southdowns are not available, we shall have to fall back upon other Down Breeds locally available, namely, in order of merit, Suffolks, Shropshires, and Hampshires, the last two of which are apt at times to give rise to parturition troubles owing to the large size of the heads of the Lambs. When the Down Breeds are exhausted, again, in order of merit, there are the white-faced Ryelands, a well proportioned Breed recently introduced into the State; the Dorset Horns of exceptional early maturity, but over-developed on the fore-quarters, and under-developed in the hind quarters; and finally, the English-Leicester, whose only defect is a tendency to tallowiness in the mutton.

I have made no mention of Corriedales as possible Sires for Fat Lambs of export standard because, notwithstanding the admitted value of the Ewes as Dams in the same connection, Corriedale Rams in my opinion are quite unsuited for the purpose, and particularly so when mated back to Merinos. A breed of comparatively recent origin, in which an attempt has been made to combine the opposing qualities of Merinos and British Long Wools, Corriedales lack essential prepotency in the things that matter to the raiser of export Lambs; they are insufficiently early maturing and fall far short of the ideal in the matter of bodily conformation.

Although it is difficult to believe, and I trust that it may not be very common, I have heard it stated that on some farms cross-bred or mongrel Rams are being used as Sires for Fat Lambs. In the circumstances I feel it incumbent upon me to state that should such a practice become at all general, it would definitely destroy any chances we may have of building up a successful Export trade in Fat Lambs. Is it necessary to stress the fact that a cross-bred or mongrel Sire is quite without prepotency, that however attractive his outward appearance no dependence can be placed upon his issue, that his hereditary endowment is a medley of warring tendencies from which almost anything might be expected except an acceptable export Lamb? If, as may happen at times, suitable Rams are not procurable, in such circumstances the would-be Fat Lamb raiser should hold his hand, and for the time being fall back upon Merino Rams, which would be replaced by more suitable Sires in ensuing seasons.

8. Size of the Fat Lamb Flock in Relation to the Normal Farm Grazing Area.

The relationship of the size of the Flock to that of the available grazing area must necessarily vary with districts and with farms: and in my opinion it is upon the accuracy with which this relationship is determined that the probabilities of financial success in the venture very largely rest. Everybody realises the danger of over-stocking, but neither can the farmer afford to see his grazing area under-stocked: I admit, however, that of the two the former is more dangerous than the latter. In this connection it is necessary to stress the fact that "over-stocking," as understood on a Station property, has not the same meaning when applied to a farm. A Station property may be said to be over-stocked when the mean number of Sheep present throughout the year is in excess of its recognised normal carrying capacity taking both good and bad years into consideration: and as such a property generally depends very largely upon edible bush for reserves, the latter is destroyed in years of over-stocking, and the Capital value of the property is proportionally depreciated, apart altogether from losses of Sheep from starvation. On an average Farm the position is very different: there is no edible bush unless an important area of non-arable land be attached to the farm, which is unusual in Mallee country; the grazing area available consists for the most part of land temporarily out of cultivation, which may carry spontaneous edible weed growth, or be partly sown to special grazing crops; of short-term pastures such as Lucerne; and of stubbles of harvested crops. Finally, no farmer can expect to take full advantage of his grazing area who does not make provision for hand-feeding over the Autumn and early Winter days, a period which, according to seasons, should not as a rule exceed more than two to eight weeks. Hence a correct determination of economically adequate stocking of an average farm should be based upon an accurate estimate of the normal carrying capacity of the various types of grazing usually available, coupled with moderate use of hand-feeding.

When I said that no farmer could afford to under-stock his holding I had in mind the question I touched upon in my opening remarks, namely, that as soon as land temporarily out of cultivation on a farm is recognised as a grazing area for revenue-earning Live Stock, all overhead charges attaching to this area, together with costs of grazing crops, must be debited against Depasturing Live Stock Accounts: and when in such circumstances the grazing area is under-stocked these combined charges raise costs per unit to such a height as to preclude any possibility of profit balances.

I propose illustrating this point briefly from the Accounts of the Mallee Farm to which reference was made in my opening remarks. During two consecutive seasons the mean number of Sheep, inclusive of Lambs, carried by this farm, was represented by 520 head per annum; and the mean grazing area on a basis of 12 months availability by 868½ acres, on which was depastured the equivalent of about half Sheep per acre per annum. Mean Flock Expenditure per annum was as follows:—

	Mean Expenditure per Annum—							
	Per Flock.						Per Sheep (including Lambs).	
	£	s.	d.	£	s.	d.	s.	d.
Natural Pasture	72	4	1					
Grazing Crops (excluding Depreciation).	235	13	3					
General Expenses (excluding Depreciation)	25	3	6					
Depreciation on Improvements and Plant	68	6	1					
Interest on Working Capital	41	19	10					
Rates and Taxes	10	8	9					
				453	15	6	17	5
All other Costs				127	5	4	4	11
Total Costs				£581	0	10	22	4

The above statement shows that on this farm mean yearly flock expenditure was £581 0s. 10d., or 22s. 4d. per head, including Lambs. If, for purposes of argument, we assumed that the grazing area had been understocked, and that instead of half a Sheep to the acre it could have carried three-quarters of a Sheep, this would have meant that flock numbers could have been increased by 50 per cent. and represented by 780 head instead of 520. In such circumstances there is no reason why the six items of expenditure given separately and aggregating £453 15s. 6d. should have varied to any appreciable degree, and costs per Sheep under this heading would have been reduced from 17s. 5d. to 11s. 7d. It is probable, too, that 4s. 11d. per head for all other costs would have been reduced in a larger flock, but as such a reduction could be determined by arbitrary estimate only, we shall not take it into account, and merely state that had the grazing area carried three-quarters of a Sheep per acre per annum instead of half, costs of upkeep of the flock would have been reduced by 5s. 10d. per annum: these facts justify my statement to the effect that whilst a farmer should beware of over-stocking his farm he cannot afford to under-stock it.

At this stage, with your permission, I propose looking backward and making brief reference to an Address on a similar subject which I delivered before Congress in 1913. The Address was entitled "The Sheep Carrying Capacity of a Lower North Farm—A Record of Seven Years' Work."* I was at the time Principal of the Roseworthy Agricultural College, and had during the seven years referred to—1906-1913—kept a careful record of all Live Stock depastured on the fields of the College Farm. It was my purpose then, as it is to-day, to persuade farmers to make more adequate use of Live Stock on their Wheat Farms, and towards that end I made use of the College records to show what could be done at the time in that direction.

In the course of this Address I showed, among other things, that the College mean Farm area—1,534 acres—had been allocated during these seven successive seasons as follows:—

	Mean Areas. Acres.
Under Harvested Crops	599
Treated as Bare Fallow	474
Under Forage Crops	149
Grazing land temporarily out of cultivation	312
Mean Farm Area	1,534

Between 1906 and 1913—a period of seven years—the mean number of Sheep, including Lambs, depastured on this area was 1,370 head per annum, that is to say, close upon 9/10th of a sheep per acre per annum on the whole farm area. If to this we add Cattle and Horses, which also had access to our grazing areas, it can be said that a farm on which over 70 per cent. of the area was under Harvested Crops or Bare Fallow, averaged during a period of seven seasons the equivalent of one Sheep per acre per annum on the whole area of the Farm. Nor can it be said that we were over-stocked, and that in consequence the Farm Flock must have been in poor condition: in those years the College was a frequent prize-taker with Sheep at the Royal Agricultural Society's Shows; its Lambs were usually sold on the farm at the highest rates current at the time; nor can I recollect the average fleece weight having been less than 10lbs. per head; all of which argues good, and not bad, condition. Finally, hand-feeding was not availed of excessively or uneconomically. In three out of the seven seasons April and May rains were sufficiently abundant to render hand-feeding unnecessary: in three others rainfall distribution was less favorable, and in April and May the flock was provided with Cocky Chaff and straw, to which molasses were usually added. In one season only—1912-13—seasonal conditions were such as to render more intense hand-feeding necessary. The number of Sheep present on the farm at the time was 1,254, and the total costs of hand-feeding £279 0s. 5d., or 4s. 5d. a head: gross receipts for the year, on the other hand, aggregated £960 13s. 4d., or 15s. 4d. per head: such costs cannot be looked upon as prohibitive, even at shorter intervals than once in seven years.

If I have quoted these figures at all, it is in the main because the College Farm is situated in Mallee country, and that in virgin condition, its land, like that of most Mallee country, would not have supported half a Sheep to the acre. I wish, therefore, to stress the fact that the secret of its acquired heavy Sheep carrying capacity is to be found in the residual influence of heavy dressings of phosphatic fertilisers systematically applied to harvested crops over a long period of years.

---

*Vide *Journal of Agriculture*, October, 1913, pages 364-390.

In this connection it should be stated that the College Farm was originally a small 600-acre farm, and that it has been gradually enlarged by successive purchases of adjoining areas: and it follows that the more recent purchases had not in my time been sufficiently long under the influence of heavy phosphatic dressings to show marked improvement in Sheep carrying capacity. Indeed, as a matter of close personal observation, I came to the conclusion at the time that from a grazing point of view our land out of cultivation was not at its best until it had carried at least 10 cereal crops dressed at the rate of 2cwt. of Superphosphate to the acre; that is to say, until it came under the residual influence of phosphatic dressings aggregating not less than one ton to the acre.

All Mallee areas are characteristically deficient in available soil phosphates, and this is particularly the case of the Murray Mallee Statistical Division generally. In the latter connection it will probably be recalled by some that the opening up of the original four hundreds for agricultural settlement was opposed by men who had had experience of the country under Station conditions on the grounds that whilst it was possible to fatten wethers on this country, it was not possible to rear Lambs or other young stock satisfactorily: this, as we know, can be accepted as practical confirmation of phosphate deficiency. It is fairly obvious to-day that high Sheep carrying capacity such as I have indicated for Roseworthy cannot be expected in relatively new Mallee areas until they shall have become very adequately dressed with phosphates in the course of normal cropping. If my Roseworthy experience in the matter holds good for other Mallee areas, namely, that maximum grazing results could not be anticipated until the pastures had had the advantage of the residual value of phosphatic dressings equivalent to one ton to the acre, then with the low dressings in current use, and intervals of three to four years between harvested crops, maximum grazing results are likely to be unduly protracted. Fortunately, since my Roseworthy days, we have found a shorter cut to the final goal, and that is systematic top-dressing of land temporarily out of cultivation and heavy dressing of specially sown grazing crops. I am aware that the latter practice involves out of pocket expenditure which cannot always be met nowadays: and the best that can be said in the matter is that in the interest of future profits grazing land should be top-dressed to the extent that personal means permit.

The grazing capacity of the Murray Mallee Farm that we have had under consideration appears to me to have been unusually low, as the following details will help to show:—

	Areas on basis of 12 months' availability. Acres.	Equivalent No. of Sheep per acre per annum. No.
Grazing Crop of Oats	489.5	0.52
Cereal Stubbles	134.5	0.61
Land out of Cultivation	244.5	0.47
Total Grazing Area	868.5	0.52

Of these figures, the most disappointing is the low grazing value—0.52 Sheep per acre per annum—of a more or less costly crop of Oats: one would have expected that at the very least a grazing crop of Oats would have supported the equivalent of one Sheep per acre per annum. The mean cost of this grazing Crop was £227 13s. 8d., including £68 10s. 8d. for the rental value of the land, and in the circumstances it would almost seem that better general grazing results would have been secured, and certainly more lasting improvement in the land, if £160 had been spent in Superphosphate for top-dressing purposes, instead of attempting to put in a grazing crop of Oats that could do no better than carry half a Sheep to the acre.

Corresponding results on the Roseworthy Farm quoted in my 1913 Address were as follows:—

	Equivalent Sheep per acre per annum.
Ordinary Pasture	1.51
Stubble Grazing	0.52
Fallow Grazing	0.25
Rape	1.86
Kale	2.46
Turnip	2.43
Vetches	2.25
Pease	2.34

There is one feature on the Mallee Farm we have had under review, a feature common in fact to all Mallee Farms, that have not yet been standardised for the intensive handling of Sheep on relatively small areas, namely, the large size of the grazing fields, which has probably exercised a limiting influence on the Sheep carrying capacity of the Farm. This farm has been exceptionally well laid out into 12 fields of the following areas:—238, 201, 160, 154, 146, 122, 121, 120, 115, 115, 84, and 79 acres. Now it is quite possible that to those without experience of handling Sheep on small areas the sizes of these fields may seem reasonable enough, not only for cropping, but for the handling of livestock as well: nevertheless, it can be stated most emphatically that apart from the use of numbers altogether out of proportion to the normal carrying capacity of the Farm, 10 out of these 12 fields are too large to make best use of moderately well grown natural pasture; and that all are too large, and some of them far too large, to make even moderate use of a well grown forage crop. The ideal in such matters is to feed off heavily and rapidly and change flocks frequently from field to field: such changes are in the interests not only of the pasture or the forage crop, but in the interests of the general health of the flock as well. Large fields and inadequate flocks lead to costly waste of feed in the growing period, and inadequate reserves for the dry times of the year. No farm is likely to be stocked up to its maximum carrying capacity until its largest field is reduced to 50 acres in area, and many fields of 20 acres are available. I realise that small fields mean increased capital expenditure, particularly as adequate provision for water has to be made in each of them: in present times, therefore, I shall not insist on the matter, but merely point to the advantages of increased subdivision and suggest that when permanent fencing is impossible light, temporary fences can be used. If in this connection I might quote my own experience I can say that at Roseworthy I succeeded in practically doubling the carrying capacity of a 120-acre field by dividing it into four fields of approximately equal areas.

I have perhaps laid myself open to the reproach that in spite of a lot of beating about the bush I have not yet stated plainly what should, in my opinion, be the size of a flock on an average Mallee Farm: nor, as a matter of fact, do I intend committing myself to any such statement. I know too well how much climate, soil, and economic conditions differ on almost every farm, and that what is possible on one is not always possible on another. I shall, however, venture a general statement in these terms: I believe that with the assistance of heavier phosphatic dressings to harvested crops, of pasture top-dressing, of judiciously chosen and handled forage crops, of occasional and seasonal hand-feeding, and finally of rational tending of the flock, it should eventually be possible for the average Mallee Farm to carry a sheep to the acre on the total area available for Grazing, including Forage Crops, without appreciable reduction in the area normally allotted to Wheat.

9. SUMMARISED STATEMENT OF MANAGEMENT.

Although I have neither the time nor the intention of writing a complete treatise on the handling and management of a Fat Lamb Flock, I propose, before closing my remarks, to summarise in as few words as possible the main points in management that have not already been broached.

At shearing time all Ewes should be carefully "Mouthed," and those with unsound mouths branded and fattened off shears: feet, too, should be examined and trimmed if necessary: Merinos in particular show long hoof growth in soft country. Dry ewes that had lost their Lambs or never were in lamb should be specially marked, and if dry two seasons in succession should be fattened off shears. Shorn ewes should be placed on good feed in order to promote rapid recovery from the strain of rearing lambs: they should be dipped four to six weeks after shearing, subsequent to which late lambs and all that had not hitherto proved marketable should be weaned, shorn, placed on specially good feed, and sold as soon as marketable. When, however, feed was in excess of the ewes' requirements and market conditions warranted it, late lambs could be marketed to advantage as late as February or March: but all should be off the farm before the succeeding season's lambing. Between shearing and mating time, ewes should have had ample time to acquire good store or half-fat condition. Mating time should be so arranged that the bulk of the lambs fall at a time when green feed was normally present in the locality, that is to say, within five months of mating. Over the greater portion of the State, and particularly in the Mallee, lambs should be made to drop in late Autumn and early Winter, say, between mid-April and the end of June, according to districts: February and March, however, are preferable for Merinos, when it is possible to provide the dams with green feed. Hence, rams should be brought into the flock some time in November: for every 100 ewes there should be not less than three rams of British Breeds, although two Merino rams will usually suffice. Rams of British Breeds are rarely satisfactory lamb-getters after the third season, and should generally be replaced. Ewes should be yarded at night once or twice a week during mating time, and it will not come amiss to keep back one or two spare rams until the third or fourth week of mating. Rams should be removed from the flock in six to eight weeks' time and placed in a special ram paddock in which they should be fed adequqately but not allowed to get too fat. At this stage the flock should be given a second dipping, chiefly as a protection against lice.

Stubbles will be available in January, and normal grazing areas can be spelled; here the ewes will do well for a few weeks provided they have constant access to plenty of good, clean water: drinking troughs are quickly soiled by sheep and should be cleaned out once a week. Towards the closing weeks of gestation the ewes require plenty of gentle exercise if parturition troubles are to be avoided: hence, occasional visits to the fallows will not come amiss provided they be not over-done. The flock should be visited periodically for fly troubles, and fly struck ewes should be treated as early as possible: the whole flock should be crutched closely prior to lambing, every precaution being taken to avoid damaging ewes heavy in lamb: they should be handled with the greatest care and not crushed unduly in the pens nor harried by dogs.

March and April will usually be critical months, during the course of which hand-feeding will be more or less necessary. Hand-feeding should not be delayed until all feed has been consumed: with sufficient roughage a pound or two of Oats a head per day should suffice: in the first week half-allowance only should be fed mixed with good Cocky Chaff. Self-feeders are best for the purpose; in their absence adequate substitutes must be devised. All ewes should reach lambing time in good condition, but not too fat. Baits for foxes should be scattered in February and March: roamers should be destroyed before lambs begin to drop.

Ewes should lamb in well sheltered paddocks, preferably in flocks of not more than 100: in large flocks they are apt to lose their lambs wholly or for undesirably long intervals: they should be protected against disturbances likely to intimidate them, otherwise Merinos tend to abandon their lambs. Lambs are dropped chiefly in the evening or early morning: hence lambing flocks should be visited twice daily. Apart from diseased conditions, parturition troubles are not usual with sheep: they are more frequent in dry than in moist conditions of weather. Merinos require assistance at times when dropping lambs to Large British Breeds.

Lambs will nibble young grass a few days after birth: and when green feed is scarce, ewes that have lambed should be separated daily from the flock and placed on specially reserved feed. At birth lambs will weigh from 1/10th to 1/12th of the weight of their dams, say 7lbs. to 10lbs. for smaller breeds and 12lbs. to 18lbs. for larger breeds: they should increase in weight at the average rate of ½lb. a day, and with good mothers even more. To some extent weather controls development: continuous wet weather retards it: given sufficiency of feed, bright, frosty weather puts on bloom.

Lambs should be tailed, and males castrated within two to three weeks of birth: if practised later, development is retarded. The lambing flock should always be kept upon good forcing feed; and carefully tended cross-bred lambs should be ready for market 3½ to 4½ months from birth: they should be handled with the utmost care for fear of bruises.

CONCLUSION.

In my opening remarks I stated that the title of my address was to some extent misleading, and that whilst I had undertaken to discuss Sheep in the Mallee, the main object at the back of my mind was to stress the extreme importance to Farmers of the State of what has come to be known among us as the side-lines of a Wheat Farm. And now I must confess that I do not know whether in attempting to do two things at once I have not fallen between two stools. After many years of careful observation, my own personal conclusion is that whatever the circumstances, and whatever the prices obtaining at the time, no Wheat Farmer in Australia can afford to overlook the assistance to be derived from Dairy Cattle, Sheep, Pigs, or Poultry, singly, or taken in the aggregate. In the difficult economic struggle of the nineties this fact was very clearly driven home to South Australian Farmers of that time: and it is in my opinion much to be regretted that a series of favorable seasons coupled with unusually high prices for Wheat should have made their post-war successors forget the painful lessons of the past. It should be obvious that no farmer can afford to lay out his plans on the basis of high Wheat prices any more than he can afford to do so on the basis of the permanency of favorable seasons: rather should he in either matter be guided by the golden mean and adhere to plans that have stood the test of time. Let us hope, therefore, that when once again our Farm Flocks and Herds shall have been successfully built up, history will not repeat itself, and that we shall not see invaluable Live Stock sent into exile and a return to the one-crop ideal.

In conclusion, I shall say that during the course of my remarks I have had to express personal opinions, fairly forcibly at times, perhaps, and, as is the way in matters human, there will be those who hold quite opposite views. In this connection I shall say, therefore, that when I am called upon to tender public as distinct from individual advice on technical matters, I ask myself two questions, namely:—(1) What is best from the viewpoint of the State as a whole? and (2) What is best from the viewpoint of the *average* farmer? and according to my lights I endeavor to act accordingly. It follows, therefore, that at times I must miss the viewpoint of the man of exceptional experience; but he, as we all know, is generally able to look after himself.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)
F. COLEMAN, J.P.

W. J. ADEY, ESQ.
H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

ROSEWORTHY.

ANNUAL REPORT ON PASTURE IMPROVEMENT, KYBYBOLITE EXPERIMENTAL FARM, 1931-32.

[By L. J. Cook, R.D.A., Manager.]

(*Continued from page* 265.)

The Breeding of English Leicester-Merino Lambs on Subterranean Clover and Wimmera Rye Grass Pasture.

For the past three seasons separate flocks of ewes have been grazed on the different series of fertilised plots, and careful records kept of the lambs produced. Flock E, consisting of 31 aged ewes, 20 maiden ewes, and 15 hogget ewes, was used on Plots Nos. 4, 5, 6, and 15 fertilised with superphosphate.

Flock I, consisting of 25 aged, 17 maiden, and 13 hogget ewes, was used on Plots Nos. 3, 7, and 8, fertilised with lime or gypsum and superphosphate. Flock G, consisting of 21 aged, 14 maiden, and 11 hogget ewes, was used on Plots Nos. 10, 11, and 13 fertilised with rock phosphate; whilst Flock K was used on the balance of plots.

The following table shows the percentage of lambs marked, and the average weight of lambs at weaning, from the three Flocks E, I, and G, for the three years.

Table 9.—*Breeding of English Leicester-Merino Lambs,* 1929-32.

Flock.	Type of Fertiliser.	Type of Pasture Grazed.	Lambs Marked. Oct., 1929. %	Oct., 1930. %	Oct., 1931. %	Average Weight of Lambs at Weaning. Jan., 18th, 1930. Lbs.	Jan. 8th, 1931. Lbs.	Jan. 5th, 1932. Lbs.		Sheep Car. per Acre.
Aged ewes	Island Rock Phosphate	Subt. Clover and Rye Grass	111	144	114	74·1	57·2	52·3	Comebacks..	3·14
I Aged ewes	Super and Lime or Gypsum	Subt. Clover and Rye Grass	111	137	124	64·7	51·7	52·0		4·73
E Aged ewes	Superphosphate	Subt. Clover and Rye Grass	90	137	106½	61·2	54·4	50·8		4·18
E Maiden ewes ...	Superphosphate	Subt. Clover and Rye Grass	—	...	80	—	—	61·9	Crossbreds ..	4·13
G Maiden ewes ...	Island Rock Phosphate	Subt. Clover and Rye Grass	—	—	69	—	—	64·1		3·14
I Maiden ewes ...	Super and Lime or Gypsum	Subt. Clover and Rye Grass	—	—	76½	—	—	67·0		4·73
KI Maiden ewes ..	Super and Lime or Gypsum	Natural Pasture	—	—	50	—	—	57·3		2·93

All the aged ewes used in the above flocks were selected similar in type and age, Leicester-Merino half-breds, and were mated to Merino rams. The lambing percentages were again very satisfactory; the light percentage in E Flock during 1929 was due to an unusual number of deaths at birth.

The maiden ewes (1929) drop are daughters of the aged ewes, grazing on these plots, by Merino rams, and were this year mated with English Leicester rams. Their lambing percentages were very fair for maiden ewes, and they produced some very fine lambs, the average weight of which at weaning was somewhat lower than could have been expected, on account of the very early ripening of pastures, and consequent irritation of grass seeds.

KI Flock is constituted of similar ewes, but grazed on improved natural pasture, without Subterranean Clover or Rye grass. As could be expected, the lambing percentages and weight of lambs has been considerably lower in this flock.

The comparison of weights and percentages show clearly that the sown pasture on cultivated land is much preferable for breeding purposes than the natural pasture, even when the latter is well fertilised by top-dressing.

DEVELOPMENT OF COMEBACK EWES ON SUBTERRANEAN CLOVER AND WIMMERA RYE GRASS PASTURE.

The maiden ewes and hoggets in the above flocks have been grazed on their respective plots from birth (Spring 1929 and 1930 respectively), excepting for a few weeks at weaning and mating times, when they were run on similar type pasture, and to further show the advantages of cultivated pasture the following graph is of interest:—

Graph 5 shows the monthly weights of Comeback ewes (¾ Merino, ¼ English Leicester), born and reared on the cultivated pasture, compared with those reared on improved (top-dressed) natural pasture since May, 1930, and also the weights of similar ewes bred in 1930, and weighed from May, 1931.

The 12 ewes in KI Flock were originally bred on clover plots, but the four hoggets added in April, 1931, were bred on natural pasture.

All were selected similar in type, age, and breeding, weighings were made as regularly as possible, and similar treatment given to the four flocks throughout the seasons, they being all subject to our system of rotational grazing.

It is interesting to note that, although the 1929 ewes started in May, 1930, at a comparatively even weight, there was a considerable difference 12 months later, and this difference has been maintained throughout the next 12 months, despite the fact that the flocks on cultivated pasture reared 50 per cent. more lambs than those on uncultivated natural pasture, as shown in Table 9. The three former flocks for the past 12 months have been an average weight of 110lbs. per head, approximately 17lbs., or 18½ per cent. heavier than the latter, which has for the same period been an average weight of 93lbs. per head.

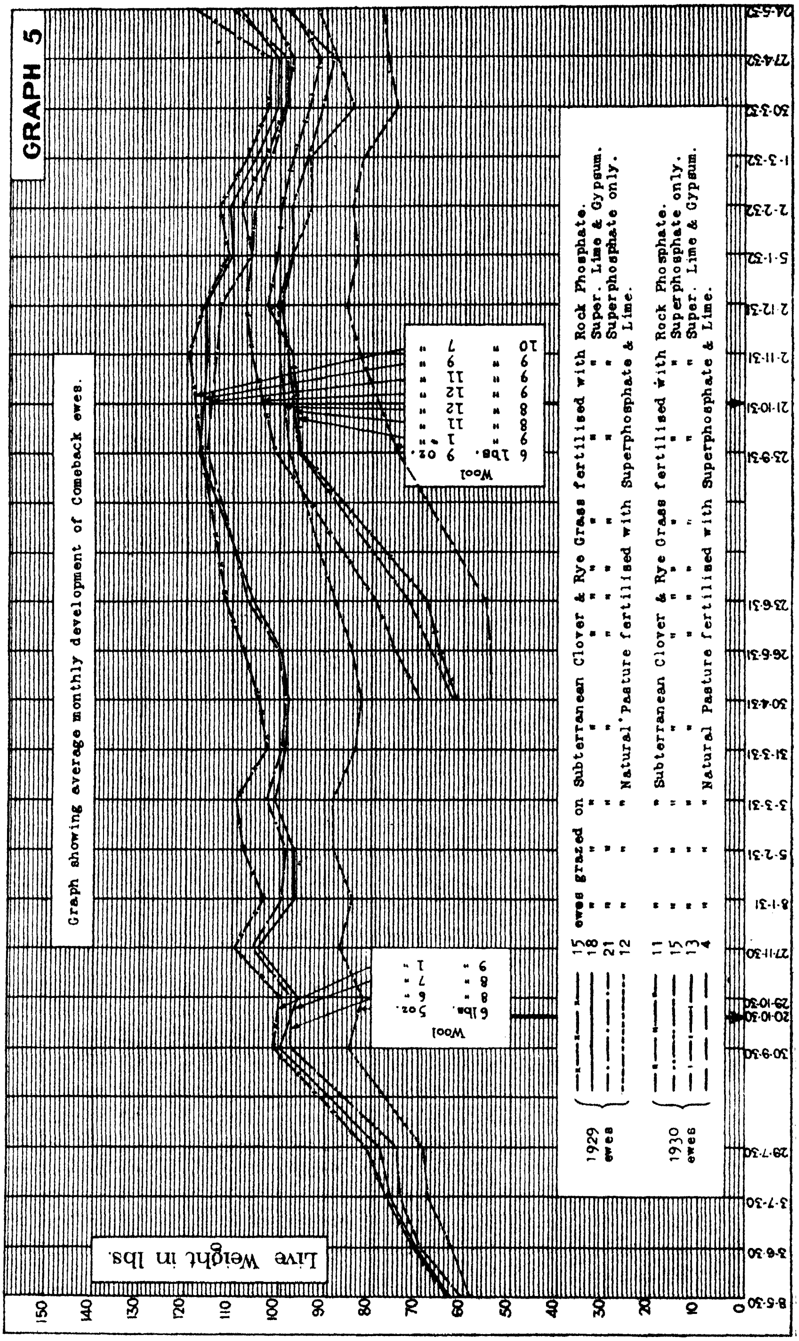
The weights of the 1930 ewes have shown a comparatively similar development as the 1929 ewes during the previous year. The 1930 ewes in KI Flock were bred on the natural pasture, and therefore at the commencement of weighing on April 30th, 1931, their average weight was somewhat below those of the other flocks. The graph shows that their weights have risen and fallen proportionately with the others, and there has been a regular difference of 22 per cent. in live weight.

The weight of wool produced from the different pastures is most marked. On the clover and rye grass the 1929 ewes have averaged 18lbs. 8ozs. wool for the two shearings, and the 1930 ewes have averaged 9lbs. 3ozs. for 1931 shearing. The ewes on improved natural pasture yielded respectively 15lbs. 1oz. and 6lbs. 9ozs. Increases in favor of sown pasture of 23 per cent. and 40 per cent.

If the graph of KI Flock is compared with those of Flocks B, C, and D shown in Graph 2 earlier in this article, a marked similarity in development and weights of wool is noticed, so that these graphs can be regarded as showing what can be expected as typical development on top-dressed natural pasture.

As regards the three Flocks G, I, and E, that have been fed wholly on Subterranean Clover and Wimmera Rye grass pasture variously fertilised, these have developed comparatively evenly, and although Flock G, grazed on pasture fertilised with rock phosphates, has been slightly in advance of the other two during most of the period the differences are not very marked. Compared with Flock I, grazed on pasture fertilised with lime and superphosphate, the difference in weights of ewes during their hogget period was 5lbs. to 6lbs. average, and during this year, their first breeding season, the difference has only been 2lbs. in live weight. The lambs produced favored I Flock, which marked 76½ per cent., against 69 per cent. by G Flock, and at weaning time I Flock lambs averaged 67lbs., against 64lbs. of those in G Flock. In wool production G Flock has produced 19lbs. 8ozs. wool per head, and I Flock 18lbs. wool per head in the two seasons.

E Flock, grazed on pasture fertilised only with superphosphate, has not varied in average live weight of ewes, more than 4lbs. per head compared with G Flock, produced 80 per cent. lambs, weighing 62lbs. each at weaning, and yielded 18lbs. 1oz. wool per head in the two seasons.



GRAPH 5

Graph showing average monthly development of Comeback ewes.

These differences are only slight, so that the actual carrying capacity of the various fertilised plots governs the productivity materially. Those dressed with lime and superphosphate have the greatest carrying capacity for the years under consideration, as shown in the final column of Table 9. These figures include all sheep carried for the whole season. The average number of ewes carried per acre for 1931-32 has been 4.10 for lime and super. plots, 3.50 for super. only plots, and 2.71 for rock phosphate plots.

Calculating from these it is found that the lime and super. plots have produced 39.2lbs. wool and 210lbs. live-weight lamb per acre; the super. only plots 33.9lbs. wool and 173lbs. lamb, and the rock phosphate plots 28.3lbs. wool and 120lbs. live lamb per acre.

With reference to the health of sheep in the above flocks, the losses during 1931-32 have been much greater than previous seasons, due almost entirely to entero-toxaemia, which affected the sheep during last winter, and early spring of the season. Of the 1929 ewes, two died during 1930-31, one in Flock E and one in Flock G, and three died during 1931-32, two in Flock I and one in Flock G. These are percentage losses of 3.7 per cent. and 5.9 per cent. in respective seasons.

Of the 1930 ewes the losses were greater, three deaths occurring in Flock I and one in Flock G, meaning a loss of 10.3 per cent. for the season of 1931-32. Against these, in the KI Flock, grazing on improved natural pasture there has been no losses during either season.

Assuming that the flocks were all composed of 1929 ewes, and allowing for losses, the top-dressed natural pasture has produced during the past 12 months 23.1lbs. wool and 76lbs. live lamb per acre, whilst the top-dressed sown pasture has produced 32lbs. wool and 160lbs. live lamb per acre. An increase of 38½ per cent. wool and 110½ per cent. live lamb in favor of the sown pasture.

Considering only the 1930 ewes, and allowing for losses, these young hoggets produced 29.03lbs. wool per acre on sown pasture, and 19.78lbs. on the natural pasture, an increase of 47 per cent. in favor of sown pasture.

SUBTERRANEAN CLOVER.

A number of comparatively large fields have been established for some years with Subterranean Clover, and a few with Wimmera Rye grass included. Manurial dressings have been phosphatic, and some of the fields have been limed in the past. The pastures in these fields have this season consisted mainly of Subterranean Clover and annual naturalised grasses, such as sterile brome, barley, and silver grasses. The grazing of fields has not been complete in every case, as a certain reserve of feed has necessarily been held back for April and May grazing, with a consequent loss of feed. However, the following table shows the grazing taken from these fields during the last eight years, and is of interest for comparison with other forms of pasture.

TABLE 10.—*Subterranean Clover, Grazing, Kybybolite,* 1924-32.

Season.	No. of Fields.	Area. Acres.	Total Feed Days.	Sheep per Acre.
1924-5	1	29·50	29,469	2·74
1925-6	3	109·00	100,794	2·53
1926-7	5	181·50	141,041	2·13
1927-8	6	231·80	208,635	2·47
1928-9	7	267·66	234,378	2·40
1929-30	7	263·71	220,071	2·29
1930-1	5	155·70	138,417	2·44
1931-2	7	237·40	238,234	2·74
Mean	—	1,476·27	1,311,039	2·43

The result from these pastures for this season, 2.74 sheep per acre, is well above the average, and equal to the best season recorded in the past, namely, 1924-5. This result is partly attributable to most fields being more completely grazed, and less held in reserve for the coming season. The average carrying capacity for the eight seasons is now close upon 2¼ sheep per acre per annum, and shows a useful and marked consistency.

Of individual fields under clover this season, Field No. 20, 35.86 acres, yielded the greatest return with 3.62 sheep, followed closely by Field No. 20C, 29.6 acres, with 3.45 sheep per acre, whilst the lowest return came from Field No. 20E, 29.6 acres, with 1.81 sheep.

RYE GRASSES AND ALSIKE CLOVER.

Trials with both Perennial and Italian Rye grasses with Alsike clover have been continued in the six-course rotation of 2 acre fields, and of recent years better results have been obtained from Perennial Rye than from the Italian. This season certified New Zealand Perennial Rye was sown, and germinated well, and made a very good stand, but the Alsike clover failed. The results of nine seasons are shown in the accompanying table.

TABLE 11.—*Grazing of Rye Grasses and Alsike Clover, Kybybolite,* 1923-32.

Total	—	40·74	28,305	1·90

The results from the series this season have been better than average. This is due to better stands of Rye grass, and to extra top-dressing with superphosphate, that has been given to the second year of pasture, causing a good growth of naturalised clovers. Alsike clover has been poor this season. In handling this pasture it has been treated as a temporary pasture of two, and in a few cases of three, seasons' duration. The average on its first year's grazing for nine seasons has been 1.57 sheep per acre, and on its second year's grazing for eight seasons its average has been 1.96 sheep. Four times it has been left for a third season, when its average has been 2.53 sheep per acre, showing an advantage in leaving the pasture for three seasons provided it is top-dressed.

It is proposed to discontinue the trial of Alsike clover, and sow the fields with a mixture of Perennial Rye grass, *Phalaris tuberosa,* White Dutch, and Subterranean clovers, during the next few seasons, and give the pasture a longer duration in the rotation.

TOP-DRESSING OLD CULTIVATED LAND.

For the past seven years fair areas of land that have been cultivated for a period of from 15 to 20 years have been left out of the cropping area, and to enhance their grazing, they have been top-dressed annually with 1cwt. superphosphate per acre, but no grasses or clovers have been sown. This has had the effect of greatly increasing the growths of naturalised grasses and clovers. The following table summarises the grazing received from this class of pasture each season:—

TABLE 12.—*Grazing of Top-dressed Old Cultivated Land, Kybybolite,* 1925-32.

Season.	No. of Fields.	Area. Acres.	Total Feed Days.	Sheep per Acre.
1925-26	1	50·00	30,097	1·65
1926–27	4	140·47	68,764	1·34
1927–28	3	102·47	76,196	2·04
1928-29	3	121·07	102,089	2·31
1929–30	4	151·83	144,242	2·60
1930-31	4	151·83	134,629	2·43
1931-32	4	151·83	123,491	2·22
Total	—	869·50	679,508	2·14

Similar land left out of cultivation, but not top-dressed, has during the past four seasons carried 1.23 sheep per acre.

As a comparison to the above, the following two tables are included to show the grazing received from similar land that has never been cultivated.

Table 13 shows the combined results of all such land that has been top-dressed, whilst Table 14 shows the results from a fair area of unimproved natural land—that is, land that has neither been cultivated nor top-dressed.

TABLE 13.—*Grazing of Improved Natural Land by Top-dressing only, Kybybolite,* 1921-32.

Season.	No. of Plots.	Area. Acres.	Total Feed Days.	Sheep per Acre.
1921-22	5	17·5	9,971	1·56

1930-31	5	19·18	6,291	0·90
1931-32	4	15·68	5,392	0·94
Total	—	722·86	182,603	0·69

In summarising the grazing results of the Farm, the areas that have been subjected to the different treatments for a number of years are collected and averaged over the various periods in the following table:—

TABLE 15.—*Summary of Grazing Results at Kybybolite.*

Type of Grazing.	No. of Years Tested.	Area. Acres.	Sheep per Acre per Annum.	Increase over No Manure. Sheep.	Increase over No Manure. Per Cent.
Subt. Clover and Wimmera Rye Grass (Expl.)	7	70·5	3·23	2·54	368
Subt. Clover (Large fields)	8	184·53	2·43	1·74	252
Improved Natural Land (Topdressing only)	11	33·91	2·21	1·52	220
Topdressed old cultivated land	7	124·21	2·14	1·45	210
Rye Grass and Alsike Clover	9	4·52	1·90	1·21	175
Non-topdressed old cultivated land...	4	43·00	1·23	0·54	78
Natural Land (Unimproved)	11	65·71	0·69	—	—

The results in Table 15 can be looked upon as a fair comparison, although it must be noted that it has not been practical to fully graze all the larger fields, especially amongst those in items 2, 4, and 6. However, as they are averaged over a number of years, the table is useful and interesting, and continues to show the advantages to be gained from Subterranean clover, Wimmera Rye grass, and top-dressing with phosphates.

SOWN WINTER GRASSES.

Among the experiments more recently commenced, 5-acre plots were established in 1929 of Wimmera Rye grass, Perennial Rye grass, and *Phalaris minor*, by sowing 8lbs. seed per acre for the Ryes and 2lbs. *Phalaris* with 1cwt. 45 per cent. superphosphate.

In 1930 a plot of *Phalaris tuberosa* was established by using 2lbs. seed with 1cwt. 45 per cent. superphosphate per acre. This seed showed rather low germination test, but produced quite a good stand of plants, that have this season provided a wealth of feed especially during the winter months. Its yield of 3.52 sheep per acre is twice as good as any one of the other three grasses under similar treatment, and this, combined with its known ability to persist under local conditions, leads us to expect some valuable results from it in the future.

This season the four plots were again top-dressed with 1cwt. 45 per cent. super. and 3lbs. Subterranean clover seed were broadcasted per acre over the plots and covered by harrowing. The Rye grasses suffered during winter from the shortage of humus, or available nitrogen in the soil, and did not give nearly as much feed as during the previous season. The Wimmera Rye was somewhat better than the Perennial.

Table 16 shows yields from these grasses for the two seasons:—

TABLE 16.—*Grazing Sown Winter Grasses, Kybybolite,* 1930-32.

Area. Acres.	Variety.	Year Sown.	Sheep per Acre. 1930–31.	Sheep per Acre. 1931–32.	Mean.
5	Wimmera Rye Grass	1929	2·47	1·70	2·09
5	Perennial Rye Grass	1929	2·05	1·48	1·77
5	*Phalaris minor*	1929	1·86	1·81	1·84
5	*Phalaris tuberosa*	1930	1·64	3·52	2·58

KIKUYU GRASS.

A small trial plot of Kikuyu grass was established in virgin soil, by planting runners of the grass in plough furrows, with superphosphate, 4ft. apart, during September, 1929. The plants took a good hold of the soil, have spread over the whole plot, and have made plenty of growth during the warmer months of the year. It produces very quick feed after summer rains, but produces little or no feed during the cold months of the year, which detracts greatly from the value of the grass to the district. No grazing record of this plot is available.

NITROGEN FERTILISER TEST.

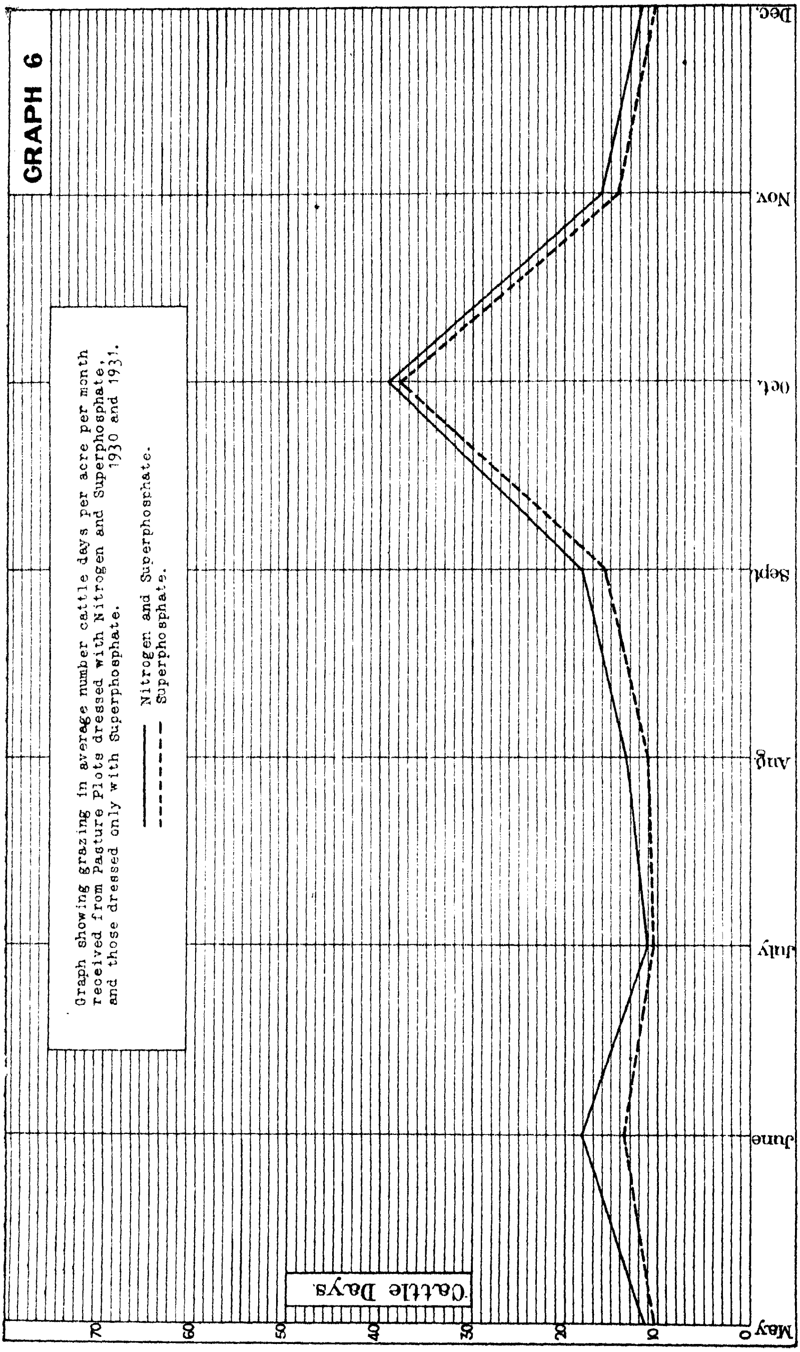
WORK was commenced in conjunction with the Nitrogen Fertilisers Proprietary Limited in 1929 to test the complete fertilisation of Subterranean clover and Wimmera Rye grass pasture, combined with intensive grazing by the milking herd. Eight 4-acre plots were established in 1930, four dressed with nitrogen as well as phosphatic fertiliser, and four alternate ones dressed only with phosphatic fertiliser.

All plots were top-dressed in May, 1930, and April, 1931. Grazing by the milking herd was commenced on June 21st, 1930, and on May 11th in 1931, and during the two seasons the plots were grazed in rotation, and complete grazing maintained. The Whakatane pasture harrows were put over the plots during August, 1930, June, 1931, and again in August, 1931. In 1930 feed was available for milkers until the second week of December, but this season this grazing was completed by November 22nd. Afterwards sheep and horses were used to completely clean up the plots. On account of the good February rains in 1932, a little grazing for the herd was available late in March. The Rye grass did comparatively well on most of these plots during this season. The following table shows the fertiliser applied on individual plots, together with the carrying capacity secured for the two seasons in cattle days per acre.

TABLE 17.—*Nitrogen Fertiliser Test on Subterranean Clover and Rye Grass*, 1930-32.

Plot.	Fertiliser per acre per annum.	Cattle days per acre. 1930–1.	1931–2.	Mean.	1930–2.
1	1cwt. 45% super. and 1cwt. 20% Sulphate of ammonia	0·59	0·47	0·53	0·48
3	1cwt. 45% super. and 1cwt. 20% Sulphate of ammonia on eastern half; 1cwt. 20% calcium nitrate on western half	0·41	0·34	0·38	
5	1cwt. 45% super. and 1cwt. 20% calcium nitrate	0·55	0·41	0·48	
7	1cwt. 45% super. and 2cwts. 20% Sulphate ammonia western half; 2cwts. 20% calcium nitrate eastern half	0·54	0·51	0·53	
2	1cwt. 45% super.	0·39	0·38	0·39	0·41
4	1cwt. 45% super.	0·42	0·25	0·34	
6	1cwt. 45% super.	0·51	0·33	0·42	
8	1cwt. 45% super.	0·52	0·43	0·48	

Table 17 shows an increase due to the nitrogen fertiliser applications of 0.07 cows per acre per annum. However, in considering the six growing months of the year, June to November inclusive, Graph 6 shows that the plots dressed with nitrogen and phosphate have produced 115.7 cattle days per acre each season, whilst those plots dressed with phosphate only have produced 102.7 cattle days per acre, an increase of 13 cattle days per acre for the growing period of each season. The graph shows that this advantage of nitrogen has been greatest during the winter months, a period of the year when increased feed is most valuable. The following table, No. 18, shows the monthly increase of cow days secured from June to November, together with the daily production of butter fat per cow during 1931, from which the monthly gain in butter fat is computed. The price per pound received at the Farm, and the value of the increase, is shown in the final columns.



GRAPH 6

Graph showing grazing in average number cattle days per acre per month received from Pasture Plots dressed with Nitrogen and Superphosphate, and those dressed only with Superphosphate. 1930 and 1931.

During the period the milking herd was fed a dry ration of hay and concentrates as well as the grazing received from the plots, so that the full value of 14s. 6d. cannot be attributable to the nitrogen fertiliser. In future it is anticipated that these plots will be sown down to a mixture of Perennial Rye, *Phalaris tuberosa* grasses, with White Dutch and Subterranean clovers, with the view of testing nitrogen fertiliser on the best possible pasture. Plots Nos. 1 and 2 are being prepared for sowing in 1932.

The Waite Research Institute has continued the trials of various grasses in pure species, and in mixtures with clovers, and has also set out, this season, small plots, testing the effect of nitrogen and phosphatic fertilisers on the natural grass, pure Subterranean clover, and a mixture of grasses and clovers sown on virgin land.

Finally, through the grant made to us by the Australian Dairy Council, preparations have been put in hand to commence field trials and seed plots, of the various strains of Perennial Rye and *Phalaris tuberosa* grasses during 1932.

In conclusion, I again wish to record the valuable assistance received from the staff of the Farm throughout the season.

OUR AGRICULTURAL OUTPUT.

[*Paper read by Mr. F. Coleman (Member of the Advisory Board of Agriculture) at a Meeting of the Saddleworth Branch of the Agricultural Bureau on July* 15*th*.]

The Federal Auditor-General in February last said:—"The only real remedy in improvement in our financial position is to increase the national income," and other financial leaders have repeatedly endorsed this statement.

The national production for 1929-30 was about £650,000,000, in 1930-31 it dropped to £450,000,000. A loss in value of wealth produced of £200,000,000 must be reflected in our financial position. Too often these figures have been overlooked. People have shown more concern about maintaining the high standard of living—a standard built up during boom years with millions of borrowed money too easily obtained and too lavishly spent—rather than concern as to how that, or indeed any living, is to be obtained.

How are we to increase our national income? In this State it can only be done by increasing development of our great natural resources, by increased agricultural output. We have the knowledge, our Agricultural Instructors are doing good work, our people are intelligent; what we need is to apply that knowledge, and to show a will to work along approved lines and the best farming practice.

Is it possible in this district to increase our exportable products? I emphasise "exportable" products, because our market is so limited that we very soon find the product almost unsaleable if confined to ourselves. Vegetables, for instance, have been grown so plentifully around the city that one can purchase almost as much as can be carried away for one shilling. Is there anything in the way of a margin of profit with fresh milk at 4½d. per gallon? But we have a market, low it may be, but still a market for all we can possibly export if of good quality.

Local Organisations.

The Agricultural Settlement Committee, in its report dated November 1st last, recommended the setting up of local organisations to urge the immediate development of better farming methods in each district. It is suggested that precise technical information be prepared by Officers of the Department of Agriculture in collaboration with Officers of the Waite Research Institute, and local committees consisting of bank managers, District Instructors of Agriculture, representatives of the Agricultural Bureau, and the local show society and business men.

Such a local development committee might consider for instance:—

The Wool Industry.—Surely we can keep more and better sheep? Our natural pastures with such excellent grasses as the *Danthonias* are too sparsely covered, top-dressing, and possibly seeding with other grasses and clovers might greatly increase the carrying capacity of these pastures, as has been done at the Waite Institute, with the result that a much greater number of stock can be carried and a heavier clip of wool obtained.

Fat Lambs are coming again to the fore; we need to keep up a more regular supply. The example of some local farmers in introducing new breeds of sheep is all to the good, and deserves every encouragement and support.

Dairying.—This is now regarded as the second greatest industry in the Commonwealth, but is open to much greater development. It has made immense strides in South Australia during the past year or two. We have been exporting butter all through the past year.

The Wheat Industry.—The main industry for the Lower North. Crop competitions have aided this industry, still there is room for reduction in costs of production, and certainly room for increased yields per acre. I want to encourage farmers to keep on growing wheat, for I feel sure it will not fail us, but let us grow the best we possibly can.

The Oat Crop.—Rather a disappointing crop during the past season, but we must find an overseas market. Such a market has been neglected; we ought to be able to grow an oat to market abroad.

Fruit, Wattle Bark, Honey, Poultry, and Eggs are all deserving of greater attention.

Such local organisations as has been suggested would avoid all guesswork, they would work on definite results, dealing with actual facts and figures, and not estimates. What, for example, is the actual cost per lamb delivered at the Abattoirs? What does it cost to produce a bushel of wheat? What money value did the hens return in eggs last season? What are the returns of each cow? The local banker knows the financial standing of each farmer; he knows who is making headway and who is not, and he can probably indicate where savings may be effected. The business man, too, because of his position, can offer sound advice. The Agricultural Instructor and the Bureau members can supply knowledge and experience so dearly bought if the individual has to find it out for himself.

DAIRYING.

I have broadly outlined the work of such local organisations, and now propose to enter a little more into detail. The average butterfat production per cow in South Australia was set down last year at 141lbs. per year. The price at present is low certainly, but it is not likely to go lower. Our butter has been landed recently in London at a time when all the European cows are in the flush of their lactation period, when thousands of tons of Irish or Danish butter have been landed on the London wharves or other ports during May, June, and July. When our peak period of production comes in September, October, and November it will only have the competition of long stored or winter and stable fed cows of Northern Europe, and naturally should command a higher price. There is the possibility that the Ottawa Conference may give some Empire preference, and we may fairly reckon on better prices for export butter between now and Christmas.

The average butterfat production per cow last year was:—Victoria 180lbs., Tasmania 143lbs., South Australia 141lbs., New South Wales 130lbs., Queensland 118lbs., and Western Australia 110lbs. Such figures can be greatly increased. For comparison allow me to give actual figures from my cows. The figures are not so good as they ought to be, and as five out of the 19 cows and heifers just tested failed to pass, the figures can be used for comparison. I include all cows and heifers that have completed their 273 days' test. These averaged 333.61bs. butterfat per cow. I could have taken 10 of these that averaged just over 400lbs. per cow, or seven that average 429lbs. The conclusion is that the State average of 141lbs. of butterfat could be raised at least 50 per cent., or up to 212lbs. per cow, without increasing the feed quantity or adding to the expense or cost in labor. Why aim at only 212lbs. when 312lbs. should be within reach of all?

How are we to improve our returns? In several ways. Clear the paddocks of useless timber, logs, boxthorn, fennell, artichoke, thistles, &c. Do not destroy shelter trees, rather increase them. Subdivide the paddocks, cows like a change of pasture however abundant. Sow grasses suitable to the locality; in this district lucerne, Wimmera rye, and *Phalaris* are as promising as any so far tried. Grow oats on the wheat stubbles for grazing, for hay, or for grain as required. Test the cows, cull out the poorer ones, use the best sires procurable, look after the young stock, and conserve fodder either dry or as silage. Feeding is most important. It has been stated that the weakest point in dairying to-day is feeding rather than breeding.

At present prices of oaten hay, crushed oats, and linseed meal I venture to say any cow can be well fed, apart from grazing, for £8 a year. Allow the cow at least two months after calving before letting her get in calf again, and if you can do it allow her two months or at least six weeks' rest ere she freshens again. A calf once a year is enough.

I believe that prices of butter are likely to rise rather than fall. There may be very little margin if any of profit at present prices. My cows during the past 12 months have returned an average of £12 17s. 4d. per cow—factory return for butterfat—nearly £3 per cow less than 1930-31. Even so I am not prepared to say there is no margin. I think there is a little, and, of course, in the sale of surplus stock there is a considerable return.

There are thousands of acres in the better rainfall areas, as well as the Lower North, that under dairy cattle would produce much more than they do now, and would support a large number of unemployed, who if not directly then indirectly would add to the value of our production and wealth.

MEADOW HAY COMPETITION FOR THE SOUTH AUSTRALIAN ADVISORY DAIRY COUNCIL.

[Judged by R. HILL, Agricultural Instructor.]

Although there were only four entries, the competitors were somewhat scattered, necessitating two days in which to complete the judging.

This was done on April 12th and 13th in dull weather, which probably helped the hay to handle better and be generally more attractive.

Entries were judged on the following scale of points:—

Suitability of plants	25
Curing	25
Stage of cutting	15
Apparent nutritive value	25
Storing	10
	100

Points Allotted.

COMMENTS BY THE JUDGE.

1. D. F. SHEPPARD.

Suitability of Plants.—A mixture of subterranean clover (*Trifolium subterraneum*), perennial rye grass (*Lolium perenne*), soft brome grass (*Bromus hordeaceus*), barren brome grass (*Bromus villosus*), and hop clover (*Trifolium procumbens*). Although this was an excellent stack of meadow hay, there was not enough of the grasses present to make an ideal mixture.

Curing.—All plants in this mixture handled well and had a splendid color generally, with the exception of small patches of bleached plants.

Stage of Cutting.—It is generally found that grasses are in a very much more advanced stage of maturity than clovers, but in this case the only objection I could find was that some of the subterranean clover was a little too far advanced.

Apparent Nutritive Value.—Palatability and general appearance were really good, but with too high a percentage of clover. I am of the opinion that the nutritive ratio would be slightly narrow, and hence perhaps cause some waste in feeding.

Storing.—Well stacked on timber in an enclosed shed.

H. A. Woolley.

Suitability of Plants.—Quite a good mixture of subterranean clover (*Trifolium subterraneum*), perennial rye grass (*Lolium perenne*), soft brome grass (*Bromus hordeaceus*), barren brome (*Bromus villosus*), and silver grass (*Festuca Myuros*).

A good mixture of grasses to clover, but the quality of the major portion of grasses is not good. Silver grass in particular does not make a good hay grass at its best.

Curing.—The clover handled well and was in good condition, but the grasses were too dry and fibrous.

Stage of Cutting.—The clover was cut at the correct stage, but the grasses rather late, and to correct this, cutting should have been done a little earlier.

Apparent Nutritive Value.—Rather spoilt by the matured condition of grasses, but the nutritive ratio was quite good.

Storing.—In open stack protected with a bag covering, but a sharper gable would make it more weather-proof.

W. T. Vigar.

Suitability of Plants.—A mixture of subterranean clover (*Trifolium subterraneum*), cluster clover (*Trifolium glomeratum*), soft brome grass (*Bromus hordeaceus*), barren brome grass (*Bromus villosus*), and silver grass (*Festuca Myuros*).

Rather too much of these inferior grasses, and the hay would have been improved with perennial rye grass or Wimmera rye grass in place of some of them.

Curing.—Color very irregular, probably due to lying some time after cutting. The whole mixture handles well, and in patches has a splendid color.

Stage of Cutting.—Grasses too near maturity, but clover good. It would be better to cut earlier, even though the clover be a little on the green side.

Apparent Nutritive Value.—The nutritive ratio appears to be quite good, but palatability has been lessened by fibrous nature of the grasses.

Storing.—In open stack, which is too wide to allow sharp enough gable to make it sufficiently weather-proof. Stack too flat on top.

F. Keen.

Suitability of Plants.—A mixture of subterranean clover (*Trifolium subterraneum*), hop clover (*Trifolium procumbens*), cluster clover (*Trifolium glomeratum*), soft brome grass (*Bromus hordeaceus*), perennial rye grass (*Lolium perenne*), canary grass (*Phalaris minor*), and silver grass (*Festuca Myuros*). Quite a good mixture, but rather too much of the inferior grasses.

Curing.—Very patchy, probably due to being left in the field a considerable time, and handles rather harshly.

Stage of Cutting.—Some of the clover quite good, but as in nearly all other cases, the grasses have been allowed to become too fibrous.

PRESERVATION

DECORATION

Apparent Nutritive Value.—Grasses too fibrous and palatability not very good and the nutritive ratio too wide.

Storing.—In shed raised on timber floor, but open to the east.

GENERAL COMMENTS.

An ideal meadow hay from our good rainfall districts should contain approximately half clover and the remainder good, palatable grasses, such as perennial and Wimmera rye grasses, Italian rye grass, or perennial canary grass (*Phalaris tuberosa*).

There are other grasses, of course, but these are the main ones likely to come into prominence in these districts, and it is to be hoped that an effort will be made by landowners to establish some of them to replace the inferior grasses such as soft brome grass, barren brome grass, barley grass, and silver grass.

It might be well to offer a warning to those who have comparatively newly cleared country that it is unwise to attempt establishing perennial grasses other than Yorkshire fog grass (*Holcus lanatus*) on raw soils.

Curing.—There is a general tendency to leave meadow hay too long in the field, causing discoloring and losses in weight, appearance, palatability, and value.

Bad weather conditions very often interfere with the making of first quality hay, but this can be avoided if growers realise that the hay only needs to be in the field for days and not weeks before stacking commences.

Stage of Cutting.—I am inclined to think that farmers are too ready to consider meadow hay as clover hay and lose sight of the fact that the grasses have some value. One repeatedly sees meadow hay spoilt because the clover has been left to a stage which the grower considers is correct for cutting, and by this time the grasses have almost reached maturity. Grasses in this stage are very often left by livestock and wasted. The time of cutting meadow hay should be judged by the grasses and not so much by the clover present.

Apparent Nutritive Value.—Pure subterranean clover hay has a nutritive ratio of about 1 to 4, which makes it rather a wasteful food for general purposes. It is for this reason that grasses should be included in order to widen the ratio, but such grasses must be well cured and not too fibrous. I know that objection is raised by some growers to grasses in hay, but should there be any trouble in getting livestock to eat them the trouble can usually be overcome by chaffing the hay. In fact I am of the opinion that much better results could be obtained from all meadow hay if it were chaffed.

Storing.—In wet districts hay should be under cover, but where this cannot be done a higher gable than generally used would be an advantage in keeping out the rain. To have a gable of reasonable height, it might be necessary to build the stacks not quite so wide.

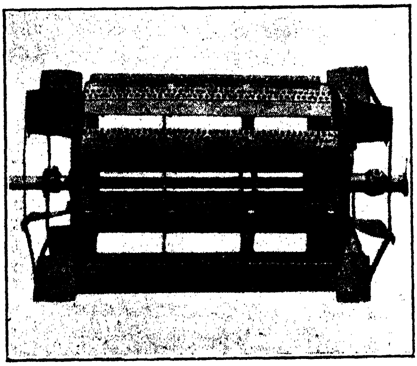
SIDE-BONE.

Replying to a correspondent who asked, "Can side-bone be cured, and also what is the cause of this trouble?" Mr. R. H. F. Macindoe, B.V.Sc., M.R.C.V.S. (Deputy Chief Inspector of Stock), says side-bone is the hardening of the lateral cartilages of the foot, the cartilage being turned into bone owing to the deposit of bone-making material into it. The actual cause of side-bone is not always clear, but it is an hereditary disease, *i.e.*, can be passed on to the offspring by his or her parents, and also may be caused by concussion. Anything which favors concussion would act as a cause, such as contracted heels and absence of frog pressure.

It is a common disease in heavy horses, but comparatively rare in light horses. Side-bone may also be the result of a blow, a tread, or a weight falling on the region of the cartilage. There is no cure for side-bones, except an operation to remove them, and this is of no benefit except to remove an unsightly enlargement. If there is lameness exhibited, due to inflammation of the cartilage, during the process of ossification, a blister, such as biniodide of mercury 1 part, lard 6 parts, may be applied There are many horses with side-bones which are workably sound all their lives.

It looks like being a tough reaping year . . .

Threshes just as effectively in early morning as at hot mid-day.



Tested and proved by hundreds of farmers with profitable results.

WHITTINGSLOWE & McQUILLAN THRESHER BARS

will get the most out of your crop and save days of your time by being able to thresh in cool weather.

READ WHAT BONA FIDE USERS SAY OF THESE THRESHER BARS.

T. H. POLGREEN & SONS, Moonta.—"Last year, 1931, we had one of your threshers put in for trial. This machine worked against two other Sun Headers, and it was always on top with returns. One cold morning it gained two bags to the round on one machine, and more on the other, so we have had the other two fitted for the coming harvest."

R. B. AYNES, Mannanarie.—"For the benefit of farmers generally I thought it was my duty to let you know how I got along with your patent thresher bars. I reaped 460 acres of tough Gallipoli, which averaged 23⅜ bushels to the acre, and was highly delighted with the sample. On 3,700 bags I had 250 bags of overweight."

G. K. SMITH, Kalta.—"I wish to state that since I have had your Patent Thresher Bars installed on my machine I have received wonderful satisfaction. They enable me to thresh early and late, and save a tremendous amount of grain that would have been lost on the old system."

C. 4269.

THE DAIRYING INDUSTRY.

[By H. B. Barlow, Chief Dairy Instructor.]

(Paper read at the Forty-third Congress of the Agricultural Bureau, September, 1932.)

To anyone interested in the Dairying Industry in South Australia, the statistical figures available for the year 1931-32, as compared with similar figures for 1930-31, are very satisfactory from the point of view of production, but although they are not available at present, I am very sorry to have to suggest that the prices realised for the year 1931-32 would not appear quite so favorable.

The figures available are as follows:—

	1930-31. Lbs.	1931-32. Lbs.	Increase. Per cent.
Butter manufactured	12,961,231	17,559,166	+35
Cheese manufactured	3,901,159	5,109,933	+31
Butter exported overseas	2,456,894	7,400,628	+201
Cheese exported overseas	—	894,847	—
Butter sold locally	10,504,337	10,158,538	—3.1
Cheese sold locally or shipped interstate	3,901,159	4,211,086	+7.6
Total number of cows in milk	79,805	90,767	—
Total number of cows dry	20,406	23,171	—
Total cows	100,211	113,938	+13
Total number of springing heifers	9,461	13,818	+46

In considering the reason for the increase in production of both butter and cheese, several factors must be taken into consideration.

1. In a country such as South Australia the prevailing weather conditions are of the utmost importance and to a great extent must be accepted as the controlling factor so far as production is concerned.
2. The number of cows milked also has a direct bearing on results.
3. The management of the cows handled—particularly with reference to feeding—is very important.
4. The productivity of the individual cows handled must be considered.

If we can for a moment forget the price factor the most satisfactory part of our operations is our ability to produce more with approximately the same number of cows and still utilise approximately the same amount of land. From the figures available, I would suggest that we have to a great extent obtained this objective.

From a casual consideration of the climatic conditions last year, one would be inclined to suggest that the season was greatly responsible for our increased output, but if the facts are more carefully analysed, it is apparent that although the season opened up well, it cut out very early in the year, and from October to February the weather was very dry and hot. Notwithstanding the very adverse conditions, our production figures did not fluctuate to anything like the extent expected, and I would suggest that to a very great extent the reason the supply held up was because the cows then in milk were treated more as a serious business proposition and liberally hand-fed during the adverse period.

The latter part of the year—April, May, and June—provided excellent seasonable conditions, and cows which had been held up during the dry period rapidly responded and greatly assisted in our increased production.

Although it will be noted that approximately 13 per cent. more cows were being handled—as dairy cows—than for the previous year, the increase in butter production was approximately 35 per cent., and in cheese approximately 31 per cent., therefore I am optimistic enough to hope that a big proportion of our increased production was due to better management and better producing cows, and I confidently look to the production figures of the next few years to confirm this belief.

The Bull Subsidies.

If, as I hope, a large proportion of our increase in production is due to better cows which have been better handled, I do not think I should omit to mention that in a large part this increase can be expected to have been brought about by our Subsidy Bull Scheme.

In my opinion the Dairy Cattle Improvement Act, which makes subsidising of Dairy Bulls possible in this State, is probably one of the soundest legislative efforts for the improvement in production ever brought forward, and if it had been in operation in one of the larger dairying States the resultant improvement in production would have been noted much sooner.

It is an acknowledged fact that the power to produce milk or butterfat is an hereditary trait and must be bred into the animal, and without question the quickest and best method to obtain a high producing herd is by the utilisation of a good sire.

Not only has our Subsidy Scheme helped dairymen to prove this contention by supplying them with approved sires at approximately half their market value, but it must also act as an incentive to those not in a position to use a Subsidy Bull to obtain the services of the best bull available to them instead of utilising any so-called bull to sire the future members of their herds.

The more I see of breeding operations the more I am convinced that only pure bred, preferably registered sires, bred from high producing cows, should be used.

To make a financial success of dairying, a farmer must—in practically every case—breed his own stock, and a reliable bull is the keystone of success.

Not only has the Subsidy Scheme been a direct benefit by supplying reliable sires, but the information obtained by the State and the individual by the consistent testing of Pure Bred Herds has been of inestimable value.

My personal opinion is that our Pure Bred Testing Scheme in this State has been and is of more value to the Dairying Industry than practically any of our other operations, and the only regret I have is that at the present moment the Dairy Branch has not sufficient staff available to carry out testing operations for the large number of pure-breeders who desire to have their herds tested.

Without a sound nucleus of pure-bred cattle to supply stock for the man on the land we can never hope for very much improvement in our average production, and in my opinion it is almost essential—both for the information of the pure-breeder and the protection of the average dairyman—that all registered females should be officially tested, if at all possible.

It is pleasing to note that the number of springing heifers show an increase of approximately 46 per cent. This is a good sign, and would seem to indicate that farmers are beginning to appreciate the fact the best means of building up a good herd is to breed it themselves.

Notwithstanding the so-called depression, it is satisfactory to note that the local sales of butter are only down about 3 per cent., whereas the local and interstate sales of cheese are 7½ per cent. higher.

The fact that South Australia has definitely commenced to open up an export market for cheese and has sent overseas over ¾ million pounds, is also very satisfactory.

Ensilage.

Whilst discussing the question of production I would like to state that I am becoming more and more impressed with the value of ensilage, either made from cereal crops or grass and clover pastures, as a supplementary food to carry our dairy cattle through the periods when insufficient pasture is available. Not only does ensilage have a marked effect on improving production when being fed, but it appears to keep the cows in better health and thus enable them to more readily respond to good pasture conditions. If fed in conjunction with a phosphate lick it would seem to definitely prevent so-called "Dry Bible," and other indications of mineral deficiency, and it has been suggested, has a tendency to lessen the incidence of Milk Fever, which is much too prevalent in this State.

QUALITY OF DAIRY PRODUCE.

Although we can congratulate ourselves that the quality of our Dairy Produce, particularly butter, has improved during the last few years, nevertheless it must be admitted that we still have a much too small percentage of Choice Quality Butter and too large a percentage of First Grade or what might be termed mediocre Table Butter.

So far as this present year is concerned, the indications are that no imports will be necessary, provided farmers will endeavor to supply good quality cream during the Summer months.

Factories, almost without exception, are better equipped to give efficient service and treatment, but notwithstanding this fact, I trust you will forgive me for reiterating that even the most efficient plant cannot produce good butter from even slightly inferior cream.

The main faults noticeable in cream are staleness and off flavors, generally accentuated by the effect of unclean utensils.

Holding the cream too long on the farm is fatal to good quality, and the failure to wash all utensils, especially separators—whenever used, either morning or evening—is responsible for practically all our inferior cream.

It is not only necessary to produce dairy products, but to obtain satisfactory results the products must be delivered for treatment in a sound condition. The generally accepted idea that any cream is good enough for the butter factory must go by the board.

It is quite late enough for us to accept the fact that the time is long past when the supplier of high quality cream or milk should be compelled by unsound methods of grading at the factory, to carry his careless co-producer, as it were, on his back.

To a certain extent the blending of good and slightly inferior cream together to make a marketable article of mediocre quality has been the accepted policy in South Australia for many years, and the result would seem to be that but a very small percentage of producers are definitely trying to deliver a really high quality product, with the result that only a relatively small proportion of our Dairy Produce, particularly butter, is really of choice quality. It is no good "blinking at facts," and the reports received by highly qualified graders must be accepted.

The technique and manufacture employed by practically all butter manufacturers has greatly improved during the last few years, and this coupled with more efficient plant and machinery has had a marked effect on improving our manufactured article, but if these more efficient methods are to be used to cloak the defects in the cream supplied by a certain percentage of farmers, it is not going to have the ultimate beneficial results which the keenness of the factory employees and the expenditure of the manufacturers deserve.

I am optimistic enough to predict that dairying in South Australia has taken a definite step from being an inconsidered side-line to becoming one of our main primary industries. If this is so it is at once essential that all those interested should do their utmost to endeavor to improve the quality of our dairy products. This object can only be obtained by serious concentration on the part of all interested.

It must be acknowledged as a fact that once we become completely self-supporting for the whole year it becomes increasingly important that we should not only be able to maintain the good quality of our butter sold in the local market, but at the same time ensure that our exportable commodity should be of high quality.

Selling a high grade product on the local market will ensure increased home consumption, and from the producers' point of view, this trade should be fostered as much as possible.

So far as our export trade is concerned, the general average quality is the controlling factor as far as price is concerned.

When South Australia had a comparatively small quota of dairy produce for export the fact that buyers were inclined to only offer 2s. to 4s. lower than the Eastern States were receiving for Choice Quality butter probably did not matter to a great extent, but with, for this coming year at least, a definitely assured large proportion of our output available for export, we, particularly as producers, must do our best to supply a high grade article to the manufacturer in order that the bulk of our exportable surplus might be of sound quality. This is the only way in which we can ever hope to receive the top price for our produce.

To a great extent the fact that our production of butter has increased greatly during the last year has quite altered the position of the supplier of slightly inferior cream, especially throughout the Summer months.

In previous years it has been the practice, during our Summer months, to import higher quality butter from the Eastern States, at a considerable economic loss to South Australia, and blend this good butter with what might be termed our inferior local article and thus utilise a larger quantity of our own product for local consumption than would have otherwise been possible. From the point of view of the producer of a sound article this statement may be a bitter pill to swallow, but it is a fact.

Without any high grade fresh butter to be used for blending purposes, we will have to depend on our own local product, and I sincerely trust that our local producers will, by concerted endeavor, so improve the quality of their raw product during the Summer months that we will be enabled to at least maintain the quality of our locally sold butter to the standard possible during the Winter months.

Admittedly, hot weather has a detrimental effect on cream quality, but it must be a sign of either ignorance or indolence if this fact is not counteracted by more careful handling and more efficient treatment.

The only really justifiable cause for inferior cream is either the effect of pastures (weed flavors, &c.) or the fact that transport facilities are not available to allow of the cream reaching its point of manufacture in a sound condition. There is absolutely no excuse for a large percentage of cream arriving at the factories in an unsound condition due to careless handling (including cleanliness, etc.), and the same statement applies to a large percentage of the stale cream coming forward.

The point I wish to stress is that having gone a long way to developing a sound dairying industry, which from the State's point of view must be a great economic asset, it is essential that we recognise the very often reiterated fact that the quality of our raw product is not all that can be desired, at least in relation to a large percentage of the factory supplies. The improvement of a very large proportion of these inferior supplies is by no means difficult, and does not represent any added expense to the individual, but does necessitate that all cream and milk suppliers, either to butter or cheese factories, do their utmost to supply a sound product. It is not the least amount of good to still think we are in a position to feel insulted when informed by the factory grader that your produce is second-grade, but it must be accepted as a fact that South Australia has for the time being at least joined the ranks of a legitimate dairying State, inasmuch as it represents a large part of our primary production, and therefore we must consider that we have become adolescent and are past the stage when an insult to our personal pride can be assuaged by sending our produce to another factory and have it called Choice.

GRADING.

We must face our responsibility and accept the position that when an efficient factory grader says our cream is inferior it is a fact and must be accepted as such, and the only reasonable method of remedying the trouble is to do our best to correct the trouble, which is in practically every case traceable to some point between the cow and the factory.

Given co-operation on your part, the Department of Agriculture is quite capable and willing to assist you in locating the trouble, and as I see it this is the only way we in South Australia can definitely place ourselves in the dairying arena with credit to ourselves and our State.

For some years I have seen this question of quality becoming more acute, and I think that with a decidedly increased interest in dairying throughout the State, representing as it does much larger financial outlays in farms and factories, the time has come when we must cease to copy the ostrich and bury our heads in the sand, but accept the facts as they are and endeavor to overcome them by concerted action and personal endeavor. Although I have apparently confined my remarks in quality to cream and butter, the position with regard to milk and cheese is practically similar, particularly as far as the producer is concerned.

MILK SUPPLY.

Probably the weakest link in our Dairying Organisation at the present moment is the disorganised state of the Adelaide milk supply. Without going into this matter in detail I would suggest that so far as the producers are concerned the position is very unsatisfactory from the financial aspect and decidedly unsound from the State's point of view.

Much milk is being retailed either by hand or through shops at prices which can be considered less than the cost of production, and it would appear as if, in order to obtain some stability a much better organisation of the distributing method will have to be put into operation.

To a great extent similar conditions have obtained in several of our other capital cities, and the methods adopted to alleviate the trouble should be carefully considered by those interested. On the surface it would appear that some system of control is essential in order to prevent the position becoming chaotic.

In conclusion I would like to make clear a statement recently made by Mr. L. T. Macinnes, Director of Dairying in New South Wales, and published in several of the local papers. The statement was as follows:—

"The official statistical estimates for the total Realisation Values of dairy produce, wool, and wheat, for the year 1931-32 are as follows:—

	Australia. £
Dairy Produce	39,000,000
Wool	29,000,000
Wheat	26,000,000

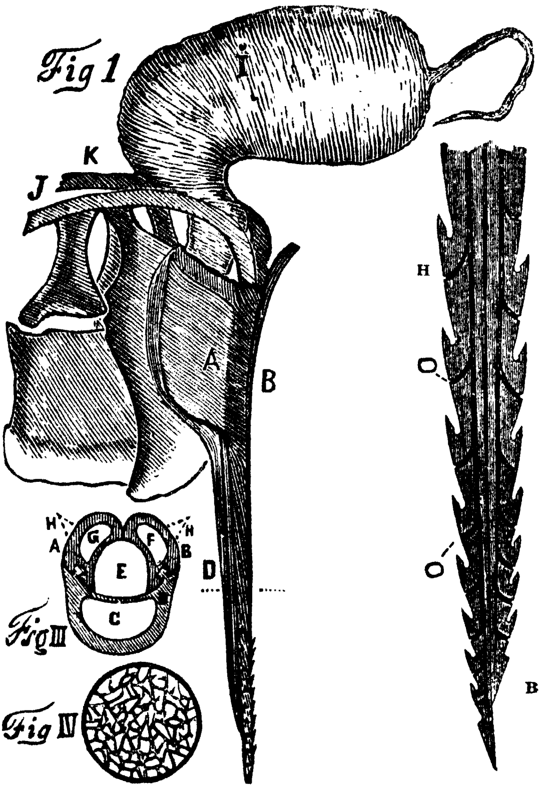
To-day dairying is the premier of all industries (primary and secondary) in Australia in regard to value of total production, numbers of persons engaged or dependent thereon, and capital invested."

In some quarters there would seem to be a misunderstanding with regard to this statement, but it will be noted that it refers to the total realisation value, that is, local sales and export sales, and not only to export sales.

BEES.—LIFE AND CULTURE.

[By R. Nosworthy, Balhannah.]

The bee, as all are aware, is the insect which produces that very nourishing food—honey. In appearance the bee is similar to a blowfly, except that it has a longer body. The male bee (the drone) can easily be mistaken for a blowfly, because its tail is round and not pointed as is the tail of a worker bee. The queen is much longer than the worker, and so can be distinguished from the rest of the swarm, although she is only one among thousands.



The Worker.

Of the bees in a hive, the worker is the most common, as its name implies. As most people know, it has a sting. This is the defence of the worker and is the tail of the bee and not the mouth as is so often erroneously thought. Take a sting and put it under a microscope and the following will be seen:—

In Figure 1, the sting is shown as it leaves the body of the bee. This is black in appearance except *part I.*, which is white. *I.* is a bladder which contains acid or poison which makes the smart that is felt. *Figure* 2 is the point or barbs of the sting, A. and B. being two sets of barbs which move alternately when worked by the muscles J. and K. in Figure 1. The barb A. is forced into the flesh and then barb B., and so on. In *Figure* 3, a cross section of the barbs cut off at D. in Figure 1, is shown

A. and B. show the barbs held in place by C., along which they slide. E., F., G., and H. are hollow tubes, through which the acid is forced at the same time as the muscles J. and K. drive in the barbs. This pumping action of the muscles J. and K. continues after the sting has left the body of the bee. By holding up a sting a drop of acid can be seen accumulating on the tip of the barbs. In taking a sting from the flesh of oneself, it should be brushed off and not pulled out. When it is pulled out, the acid from the bladder is squeezed into the flesh. It is a question of much conjecture as to whether or not a bee dies when it loses its sting. I do not know myself, but I believe that it still goes on working for a short period.

LEGS.

The back legs of a bee are fitted, as it may be said, with baskets in which to gather pollen. The legs have flat sides, over which hairs fold to form the basket. The middle legs are used to carry the pollen from the front legs to the baskets. The front legs are provided with a scraper for taking the pollen off the tongue.

STOMACH.

The bee has two stomachs, one which supplies its own needs and one in which to carry nectar. When gathering nectar from flowers, the bee stores it in its second stomach until it returns to the hive.

The worker bees have various sections of work allotted to them:—(1) Sentinels; (2) nurses; (3) scavengers; (4) retinue; and (5) outside workers.

(1) If one approaches a hive, a few bees will come out to see what is taking place; these are the sentinels. Their task is to watch at the entrance for any intruder that may come along. If a bee from another hive comes to the entrance with the intention of robbing, the sentinel immediately attacks and also warns the rest of the colony. Bees from different hives have different scents, and it is by this means that the sentinels distinguish strangers from brothers.

(2) When the eggs are laid by the queen, the nurses have to feed the resultant larvae when hatched. This work must be done properly because the young bees are the life of the colony. In raising young bees, the nurses have to provide food partly digested for the larvae. They have a special food for the larvae from which the queens are raised.

(3) When the young bees hatch out, they have to clean the cell from which they emerge. Any other refuse which may be found in the hive is also taken out by these scavengers. In addition to this, they manage the storing away of the honey and pollen as the outside workers bring it in.

(4) Wherever the queen may go, a retinue of six or seven bees will nearly always be found following. When she is laying, two examine each cell as the eggs are being deposited to see that not more than one egg is left to a cell. If two are deposited, one will be removed to another cell. It is also part of their work to feed the queen.

(5) The gathering of honey and pollen is done by the outside workers. When gathering honey, the bee travels from bloom to bloom until it can carry no more. The collection of pollen is a very interesting part of the work. The bee picks up the pollen on its tongue, at the same time making it moist. It wipes its tongue on the scrapers on the front legs, and from there the middle pair of legs take and pack it into the baskets on the back legs. Being moistened on the tongue with a little honey, it has the appearance of a tiny wad. This readily sticks in the baskets. The process is gone through so quickly that it is very hard to follow unless watched closely.

THE QUEEN.

The most important bee of a colony is the queen, there being only one queen to a hive. Hers is the herculean task of laying enough eggs to keep the colony thriving. As there are approximately 60,000 bees to a good swarm, and the average life of a —during the working period of honey collecting—is from three to six weeks, she has to lay about 3,000 eggs daily. She has to perform this task right throughout the honey season. During the winter she has a rest because the bees, not working, live for several months. She may live for about six years, but in the last season or so will not be very productive. Her life's work commences when she is from eight to 10 days old, but much depends upon her being fertilised by the drone. In mating with the drone she is fertilised for life by absorbing into her body the organs of the drone, which dies immediately on mating with the queen.

A most remarkable feature of the raising of the eggs and larvae is that the queen lays the eggs and the bees themselves do the rest. For instance, from given eggs they will raise either queens, workers, or drones. This is done by supplying various foods to the larvae as soon as hatched. In raising a queen, a special cell is constructed and a food (royal jelly) is given to the larvae in that cell. These cells are isolated and are much larger than any other in the hive. A queen takes about 16 days to hatch, the worker 20 or 21 days, and the drone 24 or 25 days.

THE DRONE.

The drone is the male bee and his only job in life is to fertilise the queen. Very often the drones are killed off by the workers as being useless.

SWARMING.

In spring, when the bees swarm, queens are raised in numbers. As many as 17 queen cells have been taken from a hive in one day to prevent it from excessive swarming, thus weakening the colony. When a young queen is hatched, the old queen takes a large number of bees to look for a new home, leaving the young one in the old hive.

Swarming bees, previous to leaving the hive, gorge themselves with honey in order to have enough food for two or three days. It is very seldom that they sting when they have only just come out of the hive.

HONEY.

The nectar that the bees collect is not fit for use as honey until it has been treated. The bees add a little of the acid from their stings. This is a preservative similar to salicylic acid. After being kept in the cells for three or four days the bees cap or cover it with a thin coating of wax. This is fit for use as honey.

WAX.

Wax is a material made by the bees. It is secreted from the joints of their bodies. Used in making the honeycomb, wax is one of the most essential things in a hive. The sense of location of the bee is wonderful. Although there may be as many as 100 colonies all in one place and every one exactly alike, a bee will come home from the fields and go to its correct hive. Shift a hive, say, 3ft., and you will see the bees hovering around where the entrance was, and they will take a long time before finding the hive.

GENERAL MANAGEMENT.

When keeping bees, the first thing to do is to give them a good home; a box that will keep out all wet, draughts, and enemies. Spiders and ants are the two worst enemies. Again, give the bees good frames in which to build up comb, because it is by these frames that the taking of the honey is simplified. It is also advisable to provide foundation comb with the frames and thus save the bees a good deal of work. Bees eat approximately 21lbs. of honey to produce 1lb. of wax. Therefore it pays the apiarist to provide wax in the form of foundation.

For purposes of taking honey the bees should be placed as near the flowers from which they gather the honey as possible, thus saving travelling and time going to and from the hive. Also place the hives as near to a supply of fresh water as may be convenient. The bee uses an unusual amount of water. The entrances should be facing the east in order to obtain the morning sun and also away from the weather.

In extracting honey, the combs are taken from the hive, the bees shaken and brushed off, and taken into a small enclosure nearby. If the honey is capped over, a knife heated in boiling water is used to remove the caps. The frames are then placed in an extractor containing revolving cages. Being turned at a fair speed the honey comes out at a tangent, leaving the combs, which are returned to the hive, empty. Care should be taken to see that no larvae are in these frames. It is quite safe to extract the honey from combs that have either eggs or capped brood.

The cappings which are cut off the combs are melted down and cleaned to obtain the wax of which they consist. It is these cappings which provide the wax for the bee-keeper to make foundation comb to put into the frames for the bees to make the comb proper. Extracting when the bees are gathering plenty of honey may be carried on every four or five days; much depends, however, on the strength of the colony.

When honey becomes scarce, it is not profitable to rob the hives, because the bees will be so weakened that they will die out. Honey is their winter supplies, and must last until next spring. By taking it when scarce they are starved.

If a large number of colonies is kept it pays to move them periodically. Also, moving them from place to place provides fresh blooms for them to collect honey and pollen. At every move fresh water should be handy. The frames should be fixed firmly to prevent rocking and killing the bees.

At times when honey is short, strong colonies will attack weaker ones and rob their honey. To guard against this, the entrances of all hives should be closed down by placing a stick across, to allow only three or four bees to come out at once. By doing this the robbers are confined to a small space by which to enter.

Always be careful to see that the swarms are free from disease. The worst of all is ''foul brood,'' and is very contagious. This disease is not of the bees themselves, but of the brood about to be hatched. The brood which is capped does not hatch out, and when the bees clean the cells, the stench is so bad that they leave it. It is first noticed by a swarm weakening very rapidly on account of no young bees. Everything in the hive carries the germs of the disease, so that the only safe and sure way of eradicating it is by smothering the bees and then burning everything that has been infected.

SOLUBLE SALTS IN NON-IRRIGATED VINEYARDS.

[By A. R. Hickinbotham, B.Sc. (Chemist), and J. L. Williams, R.D.A. (Lecturer in Viticulture), Agricultural College, Roseworthy.]

Introduction.

During the last few seasons numerous reports have been received of partial or complete failure of vines in portions of vineyards in certain non-irrigated areas. In some cases damage was confined to partial defoliation, in others fruit was unsaleable, and in bad cases the vines got worse each season and finally died.

The first indications of the trouble were scorching of the tip and edges of the lower leaves, which slowly worked inwards until only the main ribs remained green; later nearly all the leaves were sometimes affected. New growth became weak and spindly, the margins of the leaves turning brown before they were fully formed, and in many cases the berries failed to ripen. The same vines were generally more seriously affected in succeeding seasons.

Samples were obtained from affected vines and soils of parts of the College vineyards and certain vineyards near Lyndoch, and an examination of these showed the cause to be soluble salts.

The Salt Content of Lyndoch Waters.

The affected area at Lyndoch consists of flat land along both sides of a creek. Underground water stands at a depth of about 9-10ft. Analyses of water taken from the creek above and below the area, at points about two miles apart, and from a well near the upper end of the area (depth to water 9ft.), are given in the following table.

Table I.—*Lyndoch Creek and Well Waters (Parts per 100,000).*

Sample.	Total Salts.	Cl.	CO_3.	HCO_3.	SO_4.	Ca.	Mg.	Sodium Chloride	pH
Creek above..	157	45	2	51	9	8	9	74	8·24
Creek below .	344	122	3	54	26	14	20	201	8·05
Well water ..	180	56	2	38	13	9	8	92	8·12

Note.—Sodium chloride (common salt) = chloride x 1.65.

From the table it will be seen that the water of the stream has accumulated salts in passing through the area, and this accumulation must consist of the salts in the drainage waters of the adjacent flats. Further, the average concentration of salts in the drainage waters received by the stream must be greater than that of the stream. Sodium Chloride is the most important of the salts present, and the percentage of this increases from 46.6 per cent. to 58.4 per cent. in passing through the flats. It is interesting that sodium chloride does not appear to the same extent in the salts occurring in the top 3ft. of the soil (Table II.), but that the increase in chlorine content of the canes of affected vines is most marked (Table IV.).

The importance of this salt content may be judged by comparison with irrigation water. With the latter, damage to the soil and the crop may result from water containing less than 70 parts per 100,000 of the ordinary soluble salts (1), but the kind of salts, and the nature of the soil will considerably modify any standard set. Californian results indicate that, where the salts are manly chloride and bicarbonate of sodium (as in this case), water containing more than 60 or 70 parts should not be applied in most cases (2). From a general survey of irrigation waters, Harris and Butt concluded that, under average conditions, more than 100 parts of sodium chloride, or 400 parts of mixed salts, are dangerous (3). The limit generally accepted in South Australia is 100 grains of total salts per gallon, which is equal to 143 parts per 100,000, the principal salt in our waters being, usually, sodium chloride.

A comparison of the results of analyses given in Table I., and the conclusions drawn from them, with the figures just quoted, indicate that the water of the Lyndoch area has a dangerously high concentration of salts, so that any rise of this water in the soil may be expected to lead to serious salt trouble. Therefore, surface evaporation must be reduced to an absolute minimum by maintaining a surface mulch, and by keeping down weeds during spring and early summer at least.

SOLUBLE SALTS AND pH OF AFFECTED SOILS.

The concentration of salts in the soil of affected patches, and their pH values, are also high, as shown in Table II.

The edge of an Affected Patch.

The pH of a soil is a measure of its acidity or alkalinity. Until recently it was considered sufficient to know that a soil was acid, or that it was not acid, but actually it is often found desirable to know just *how* acid it is. A few years ago no satisfactory method of measuring this was known, but it is done now by means of the pH scale, the symbol "pH" standing for acidity measurement just as the symbol "%" stands for per hundred measurement. That is, the pH scale measures the degree of acidity or alkalinity of soils or other substances. It has been found that excessive alkalinity is as bad as excessive acidity.

Acidity and alkalinity are opposed properties, and by mixing acid and alkali (say spirits of salt and caustic soda) in proper proportions, the characteristic properties of each are destroyed and the mixture is then neutral. Soils range on the pH scale between about 4 and 9.5; those of pH 7 are neutral, those below 7 are acid, while those above 7 are alkaline. Most crops do best with the soil nearly neutral. Very acid soils of pH about 4 or 5 give poor results until their pH is raised near to 7 by liming (lime being alkaline destroys some of the acidity). Gypsum will not correct acidity, because it is a neutral compound of lime and sulphuric acid, formed by the blending of these substances in the proper proportions.

At a pH above about 9 the soil is at the other extreme to acidity, being then too alkaline, and crops again do badly or are killed; some means of lowering the pH of the soil must then be devised. The application of acids, and of sulphur (which is converted to sulphuric acid by bacteria), have been used successfully, but are expensive. Gypsum, which acts in this case by reaction with the soda compounds causing the alkalinity, forming less alkaline or sometimes beneficial substances, is also effective, but large dressings may be necessary. These methods take perhaps two to three years or more to give their full effect.

Table II.—*Content of Soluble Salts (Parts per 100,000), and pH Values, of Some Affected Soils.*

Soil.	Depth of Sample.	Total soluble Salts.	Cl as Sodium Chloride	pH.	Remark.
A	0–8ins.	146	18	9·03	Variety Shiraz, affected for several years.
	8–20ins.	180	21	8·82	
	20–36ins.	288	45	9·06	
B	0–1ft.	98	13	8·90	Variety Mataro, affected for several years.
	1–3ft.	200	48	9·14	
C	0–1ft.	74	13	8·90	Shiraz and Doradillo affected, Grenache comparatively unaffected. First noticed last season.
	1–3ft.	102	10	8·93	
D	0–1ft.	80	13	8·48	Grenache vines over 45 years old, reported not affected.
	1–3ft.	142	28	8·07	
E	0–1ft.	76	20	7·95	Land never under vines, sample taken 35yds. from D.
	1–3ft.	70	10	7·99	

Note.—The reading obtained for the pH value is somewhat low when soluble salts are present.

Tolerance of the Vine for Salts.

A very extensive study of salt troubles has been made in California, and observations made there indicate that grapes are one of the most resistant fruit crops to soluble salts. They were found to grow well in soil containing 77 parts of sodium chloride, or 286 parts of total salts per 100,000 (4). In Morocco, which has a climate very similar to ours, grapes have been found to be unaffected by 60 parts of total salts in the surface soil, but the vines languished and became unprofitable with 80 parts in the surface soil and 270 in the subsoil, while vines were dead with 170 parts in the surface and 370 in the subsoil (5).

Salt Content of Affected Local Soils.

The soil samples from affected patches (Table II.) were taken in April and May, and it is possible that the concentration of salts in the surface 3ft. has been reduced since mid-summer when the vines were affected. Sodium chloride, in particular, moves readily with water in the soil. But, if the concentration shown is the maximum reached during the year, it is still excessive in comparison with the limits just quoted.

Local observations suggest that different varieties of the vine vary in susceptibility. Doradillo appears to be particularly susceptible, while Grenache is possibly the most resistant variety grown locally. The response to conditions by varieties mentioned in Table II. is in agreement with this.

The Importance of Lime.

The percentage of lime in the soils of affected patches, and especially that occurring as carbonate, is low, as shown in Table III.

TABLE III.—*Lime and Magnesia in Affected Surface Soils (Hydrochloric Acid Extract).*

Soil.	CaO. Lime.	MgO Magnesia.	Carbonate.	Remark.
A, 0–8in. ...	·31	·23	trace	Badly affected for some years.
B, 0–1ft. ...	·23	·38	trace	Badly affected for some years.
C, 0–1ft.....	·65	·56	low	Recently and less seriously affected.

A soil has a much better chance of resisting salt damage if it is well supplied with lime, particularly when it contains some carbonate which acts as a lime reserve. These soils are not well supplied. It will be noticed, too, that the effect of the salts is in proportion to the deficiency of lime.

It is difficult to state a figure which would satisfactorily represent a sufficiency of lime—probably near .5 per cent for these soils would be a minimum—but so much depends on conditions and the form in which it exists in the soil. Sufficiency should be measured by the proportion of clay combined with lime rather than by the total amount of lime present.

Showing effect on Vines in comparison with Healthy Vines.

Briefly stated the fine particles of clay can combine with lime, soda, magnesia, and other metals to form a lime-clay, a soda-clay, and so on. In a good soil the great proportion of the clay occurs as a lime-clay. When soda salts occur in the soil, the lime-clay, by a chemical reaction, exchanges its lime for soda, and the bulk of the clay may then occur as a soda-clay. If the original soil was was well supplied with lime, this must happen more slowly.

Lime-clay is loose and friable and easy to work, is nearly neutral, easily penetrated by water, not sticky when wet, and naturally maintains favorable conditions for plants. A soda-clay is very much the opposite, being dense and heavy, setting like a brick, very hard to break up when dry, sticky or even pasty when wet, and is penetrated by water very slowly; when wet it is definitely alkaline (pH about 9 or higher) and it forms a most unfavorable medium for plants. In the salt affected parts of this area, and to a lesser extent over most of the area, the clay, by reaction with the soda salts, has become largely a soda-clay, and the soil has these undesirable characteristics.

How Soils May be Improved.

The free soda salts can be removed from the soil by washing them out—rain passing down through the soil will do this—but the soda-clay can only be changed to a lime-clay by offering the clay particles an excess of lime with which they can combine to replace the soda. Further, this change can only occur readily with lime in soluble forms so that it can travel in the soil moisture to all the particles.

Improvement in these salt patches, therefore, can only be effected by adding lime, either in an already soluble form, or in a form in which it can become soluble by natural reactions occurring in soils. Under the best conditions replacement of soda will be slow—a matter of years for the full effect to develop. Gypsum meets requirements well; next best is quick or slaked lime, then very finely ground limestone. Excepting gypsum, the other forms of lime soon become carbonate after application, and are then insoluble until further reaction with more carbon dioxide occurs, when soluble bicarbonate of lime forms. The necessary carbon dioxide is formed from decaying vegetable matter, so that these forms of lime require the soil to be well stocked with humus. This can only be assured by using stable manure or green manuring. It is possible for lime already in the soil to be relatively ineffective, because sufficient carbon dioxide cannot be produced; in such a case green manuring may be all that is necessary.

In some cases it is perhaps improbable that correction can be brought about economically, but in many cases small dressings of 1-2 tons of gypsum per acre have a really wonderful effect on the character of similar soils. Reclamation of these patches should be approached on an experimental basis by applying gypsum (or lime) at the rate of 1-2 tons per acre, and/or green maure, to a small area and noting the amount of improvement. The dressing should be applied to the cultivated soil and harrowed in; it will penetrate down by the action of rain. If ploughed in it will not be well distributed, and does not affect the surface soil which is most important. Once the surface is in good trim, the soda-clay in the subsoil is little disadvantage (6) except that it stops some water from soaking down. This improves as the lime works down (7).

Risk of Extension of Salt Damage.

The problem presented by the salts of this area may be summed up as follows:—
So long as salt is allowed to rise in the soil, the soda-clay will increase, and less and less rain water will pass through the soil to wash the salt back again; the soil will get progressively worse.

With lime and organic matter added the rain will pass down more easily, taking the salts with it, and further improving the penetrability of the soil each winter, so that more and more rain can pass through; the amount of salt reaching the surface will get less each summer, and the soil will steadily improve.

Drainage.

The problem is, of course, identical in most respects with that encountered under irrigation, where drainage is the first recommendation. In this case drainage does not appear an economic solution at the present time, though possibly it is the only really effective one. To get full effect from drainage, however, water for flooding must be available. Again, the area was cropped for a long time before trouble showed up; this encourages the belief that if controllable conditions are swung a little more in the right direction the rise of salts can be satisfactorily checked.

Effect on Composition of the Vine.

The main effect of the soluble salts (chiefly sodium chloride) on the composition of the vine is in the amount of chlorine (and possibly sodium) in the canes. The quantities of starch, sugar, and nutrients were found to be almost identical in affected and normal canes, but the amount of chlorine in affected canes was several times that in normal ones, as shown in Table IV.

TABLE IV.—*Ash and Chlorine in Vine Canes (Per cent. of Air-dry Cane).*

Sample.	Condition.	Ash.	Chlorine	Remark.
College Shiraz, 1931.	Affected.	3·71	·36	Practically bare in December.
“ “ “ (check)	Normal.	2·97	·06	Average yield.
College Shiraz, 1932......	Affected.	3·39	·35	Practically bare in December.
“ “ “ (check)	Normal.	2·97	·095	Average.
Lyndoch Shiraz	Affected.	3·10	·325	Not picked, defoliated, (soil C).
“ “ (check) ..	Less affected	3·13	·22	Fruit picked, leaves scorched.
College Shiraz	Normal.	2·68	·06	Very good block.
College Shiraz	Normal.	3·10	·085	Poor vines.
Lyndoch Mataro	Affected.	3·45	·36	Not picked, defoliated, (soil B).
“ “ (check) ..	Normal.	2·52	·06	Yielded well.
College Mataro	Normal.	2·40	·055	Fair old vines.
College Mataro	Normal.	2·60	·06	Good young vines.
College Grenache.........	Normal.	3·06	·08	
College Car. Sauvignon ..	Normal.	2·39	·04	

The table shows that all seriously affected vines contained more than .3 per cent. of chlorine in the canes, while all normal vines contained less than .1 per cent. A partly affected sample contained .2 per cent.

Young Canes and Bunches from Affected and Normal Vines.

CANE ANALYSIS A TEST OF SALT RISK.

From these figures it would seem probable that the vine itself is a much more reliable indicator of the approach of salt trouble than the soil. It is much simpler to take cuttings from a dozen vines than to take even one soil sample. The cuttings represent the actual effects of the soil constituents on the vines over the area sampled, and to whatever depth the roots penetrate. Therefore, examination of the canes would appear to be a more reliable guide to conditions.

The variation in chlorine content of the canes appears from these analyses to be much more pronounced and clearly defined than the variation of salts in the soil. Further, the content of salts in the soil varies, sometimes rather rapidly, so that soil samples need to be taken at the right time. On the other hand, cuttings can be taken at any time up to pruning.

It is suggested that an examination of canes for their chlorine content, applying the limits indicated above, might prove a useful guide to salt distribution, and could be used as a simple, regular check on doubtful areas, as well as a guide to the benefit (if any) obtained by efforts at correction. In these analyses chlorine in canes was determined by the A.O.A.C. method (8); the content in the ash was unreliable.

SALT RISK AND CULTURAL METHODS.

The rise of salt that has often occurred when land was placed under irrigation and planted to vines and orchards has been generally ascribed entirely to the irrigation. From this investigation there appears to be some evidence that the cultural methods associated with these crops may be the cause of some part of the trouble.

CONCLUSIONS.

1. Drainage, which is the most reliable method of correcting these conditions, is costly and not an economic solution here at the present time.

2. It is unlikely that any treatment will recover the worst patches, and these might most profitably be given over to alkali resistant crops.

Those generally recommended are lucerne (when once started), berseem, barley and rye, millets and sorghums, rape, beet and mangolds, oats and sweet clover (*Melilotus alba*). Forage and cultivated crops only are advisable.

3. Every effort should be made to reduce surface evaporation, with a consequent rise of salt, by maintaining a surface mulch at all times when evaporation can take place, and by keeping weeds, &c., down.

4. Stable manure where possible, and green manure, are advisable to open the soil and improve its texture. This will permit rain to wash the rising salts down beyond root reach, and will make cultivation easier.

Decomposition of this organic matter will provide carbon dioxide to aid in removing soda as bicarbonate, and it will help to distribute all lime available.

Organic matter is of comparatively less value when lime is deficient.

Melilotus alba is salt resistant, a legume, and its roots penetrate deeply and decay quickly, opening the subsoil. It has been widely used overseas for this purpose, but in our conditions King Island Melilot would probably give better results.

5. As much rain water as possible must be made to penetrate down through the soil to carry salt down. This can be effected by breaking up the soil before the winter rains, by organic manures, and by gypsum or lime.

6. Dressings of gypsum or lime should be tried experimentally. These will, at least, make cultivation easier and permit the breaking up of the soil before winter. It is possible that such dressings will correct most of the trouble within a few years.

7. After dressings, cultivation must be shallow to avoid bringing up unchanged soda-clay to the surface.

RED COMB EGG ASSOCIATION.

OFFICIAL SINGLE TEST

EGG-LAYING COMPETITION, 1932-33.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens, 243—Section 1, White Leghorns—180 birds. Section 2, Any other Light Breed—6 birds. Section 3, Black Orpington—48 birds. Section 4, any other Heavy Breeds—9 birds.

Twelve Months Test. To start on April 1st, 1932.

Section 1—White Leghorns.

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR NOVEMBER.

[By CHAS H. BEAUMONT, District Horticultural Instructor.]

Control of pests will be the main work of the month in the orchard and vineyard. Neglect of precautions may mean the loss of the crop and perhaps of the tree or vine.

For oidium, dust the vines with sulphur; a little lime is an advantage in the spreading. If downy mildew is noticed bordeaux must be used at once. Young vines may need protection from cut worms, which work at night; dust or spray with arsenate of lead.

In the orchard, codlin moth will need most attention, and we rely mainly on arsenate of lead to check this pest, and the fruit must be kept covered during the growing period. Bandages are a considerable help, and the new type chemical bandages do not require to be examined very often, but ordinary bandages of bagging must be cleaned up fortnightly at least. Arsenate of lead will stop cherry slug or pear slug; this pest attacks other trees so that all must be treated.

Aphis has been troublesome again and may still need to be sprayed with black leaf 40, or dusted with nicodust. This will also check thrips. Lime sulphur will be used on apples and pears to control scab or black spot and a cool day should be chosen for the work. Pure water is necessary for diluting lime sulphur solutions.

It is good practice to thin out clusters of apricots and peaches, if we want fruit of quality and appearance.

Cultivation of the soil is most important; the soil should be worked down to fine tilth, and no weeds allowed; this applies especially close to the trees. Strawberry beds should be free from weeds and will be helped materially by a covering of mulch. Punnets should be filled equally with berries of one size and quality.

See that young trees and vines do not suffer for want of water, and if the big trees need water, see that they get it in good time, and loosen the soil as soon as possible afterwards.

Boxes and picking equipment should be clean and ready for use.

Dehydrators, trays, and racks should be got ready at first opportunity.

TRUSTEESHIP WITH SECURITY

RAPIDLY INCREASING NUMBERS OF PERSONS ARE
ENTRUSTING THEIR ESTATES TO THIS COMPANY

WHY?

BECAUSE they do not have to fear loss of assets.
BECAUSE they know the Company is impartial and will live to complete its duties.
BECAUSE the administration of Estates in the care of the Company is carried out promptly, efficiently, and economically.

DEPARTMENT OF AGRICULTURE.

Bulls that are purchased under regulations of the Dairy Cattle Improvement Act, and upon which Government pays a subsidy, are available, for two years after purchase, to serve a certain number of outside cows.

The following list, compiled by the Department of Agriculture, shows the names of such bulls and of the people who own them, and indicates also the months until which the respective owners will be prepared to make the services available.

As will be noticed, the distribution of subsidised bulls is now fairly general throughout the State; hence, many of those persons, who in the past have found it difficult to get the use of a good bull, should not have much similar trouble in the future. And here let it be stated that everyone of these subsidised animals is a registered purebred and from a dam of proved productivity under Government official test.

The maximum service fee is 10s. per cow.

For the information of cowkeepers, it is pointed out that, although the addresses as given in the following list are those to which application should be made for the services of the bulls, the bulls themselves may, in a few instances, be located elsewhere.

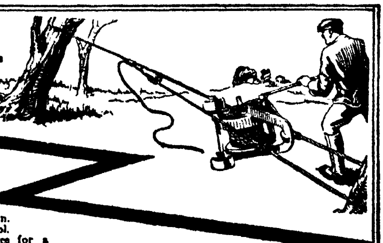
TEARING THEM OUT



is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed, it develops the power of 260 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

CONSERVATION OF FODDERS.

[By A. C. WEBB, Paruna.]

Murray Lands East, Paruna, September 27th.

It is only during seasons of periodical droughts that farmers turn their attention to the all-important question of fodder storage. Many farmers do not give this important matter due consideration from a business point of view. While seasons are bountiful we are apt to forget the bitter lessons learned in drought years, instead of availing ourselves of the opportunity of conserving a reserve of fodders for these lean periods. An important operation of farm activities should be the conservation of fodders of some description.

Taking into consideration the fact that the last two seasons have been very favorable for the storage of fodders, one cannot help noticing the small surplus stocks held in reserve on many farms. There were some farmers, who, owing to financial difficulty, were unable to cut much hay because they had to gather every bushel of wheat to meet their creditors; such a thing should be avoided if at all possible, because it does not pay. Often the remark is heard that farmers have to turn their horses out, at the completion of seeding, owing to lack of stable feed. This is very serious and shows lack of good management; one cannot dispute the advantages to be gained by fallowing as early as possible after seeding is finished. By having to wait until the feed is plentiful enough in the paddocks to start fallowing, the result of the next year's crops will be considerably reduced.

There are various fodders obtainable in this district, that if stored and protected from the weather and mice, will prove valuable in lean years.

VARIETIES OF FODDERS.

The three varieties of fodders generally available in this district are hay, grain and ensilage.

In good seasons the conserving of hay does not involve much expense, because where hay is plentiful it is cheap. The interest lost directly on a reserved stack while good years continue, will not amount to many pounds, but the value of that amount of capital invested, will be many times doubled when a drought occurs. To assure a reasonably good hay cut, more attention should be given to the preparation of land, such as clearing off all stumps, early fallowing, thorough workings, heavier seeding and heavier dressings of super, combined with early maturing cereals and early sowing. I favor small paddocks for this purpose, handy to the homestead if possible.

There are two kinds of hay from which to choose; wheaten and oaten; some favor the former, others the latter, according to their own liking and requirements. For a reserve stack I prefer wheaten hay, cut while the plant is in the flowering stage, and still a good green color, it preserves well and comes out of the stack years after in good order and sweet, providing it has been handled well from the binder, and stacked to at least 18ft. high to the sheaves, with a good roof and covered as soon as possible with straw.

Oaten hay is preferred to wheaten hay for general purposes, but should be cut when the grain is showing a golden tinge. Green oaten hay tends to have a bitter taste and stock will not eat it readily. I do not advise stacking oaten hay for a reserve, the grain being well developed when the crop is cut encourages mice and without a mouse proof fence the vermin soon eat their way through a stack and thus damage the lot. Should one not be in the position to erect a galvanised iron mouse proof fence, then stack wheaten hay cut green.

GRAIN FODDERS.

I favor oats for horses and sheep, barley for pigs, and wheat for poultry. All realise the necessity for oats in crop rotation for the successful growing of wheat, and it provides an opportunity for storing oats for use in lean periods. Storage can be provided in a variety of ways. Usually discarded tanks are to be seen on most farms, these are very useful for this purpose, and are ideal for keeping the grain dry and free from vermin and the ravages of mice. A 3,000 gallon tank will hold approximately 140 bags. Should tanks not be available, the writer recommends storing the oats in bulk in a dry shed; by storing them this way they require only half the space as when stacked in bags, thus saving considerably in cornsacks. Care should always be taken to make sure of retaining sufficient food for the requirements of more than twelve months. The thrifty farmer will also pay attention to the gathering of dry fodders, such as cocky chaff and straw, thus backing up his hay and grain supplies, especially in dry seasons. With a good straw stack on hand, one is then able to cover the reserve stacks of hay promptly, before the roof is damaged.

ENSILAGE.

Now that the farmers of this district—in common with the farmers of other districts—have adopted mixed farming in conjunction with cereal growing, this class of fodder is well worth consideration. The making of ensilage is very simple, only consisting of placing green succulent fodder in a silo, pit or stack, and then weighting it down.

This form of conserving fodder has not been practised by farmers in this district. In other parts ensilage making has been adopted for a number of years, and has proved a success.

There are two kinds of ensilage, sour and sweet. Although certain modifications of temperatures admit of subdividing these, crops cut when immature, and at a time when there is plenty of moisture, develop more acidity in the stack and temperatures do not run so high. On the other hand more matured fodders contain less moisture, thereby developing less acidity and run to a higher temperature. With higher temperatures there is a greater loss of nutritive materials.

Sour ensilage is considered the best. It should be of a pale green color with a slight acid flavor. Should the material be dry or the weather rather warm and dry, water should be applied to every layer as it is built in the pit or stack. A feature in the making of ensilage is to guard against the access of air, care should be taken to make sure that sufficient weight has ben put on the stack. Success in making ensilage is dependent on cutting the forage whilst still green and succulent, carting the material to the silo or stack the same day as cut, placing at least 4ft. of material each day on stack, completing the erection in 8 to 10 days. As soon as stacking is completed, add the weight.

Stones, stumps, fencing posts or timber prove suitable for this purpose, sand could also be used. The heavier the weight used the better the results, particularly when stack ensilage is being made. The chief feature of this fodder is that it is the nearest approach to green feed and is, therefore, an invaluable food for dairy cows and breeding ewes. Ensilage proves its greatest value in summer and early winter before there is any greenfeed. It keeps the stock in excellent condition and adds considerably to one's income.

COSTS OF PRODUCTION.

[By E. D. SYMON, Loxton.]

There are many farmers who have had a longer experience and have a more expert knowledge of the farming industry than I can claim, and I do not feel that I can contribute anything original to the discussions on farmer's affairs. For whether I have been right or wrong, I have felt for a number of years—before we were troubled with series of droughts or the fall in the price of wheat, that costs of production were perilously high, or if you like, that the margin between costs and prices was very small. Moreover, a situation that is probably going to arise, is that prices will rise and the question of reducing costs will be forgotten. It seems to me to be important that this should not happen. Farmers will have to keep a sharp eye on anything that affects their costs, particularly legislation; otherwise, there is not the slightest doubt that in the future there will be as little margin between costs and prices as there was in the past.

I have no intention of tackling the question of what it actually costs to grow wheat. I wish to base my remarks on the assumption, and I should imagine we are all agreed on this point, that wheat cannot profitably be grown at present prices—there is a gap which somehow or other has to be closed. It may be impossible to close the gap completely. Under present conditions it is difficult to see how wheat can be produced at 2s. 6d., but the probabilities are that sooner or later prices will rise—if they do not then the whole world is in for some very unpleasant experiences. But what the wheat industry wants—and this is a point I would emphasise—that costs should be reduced not merely to ease the present position, but to meet that rise. It is unlikely that wheat prices will make a spectacular rise. What there will be will probably be small. It is, therefore, urgent that as soon as any rise comes we shall be in the most favorable position to produce wheat profitably, pay off some of our past debts, and establish some reserve to replace our plant. That is another urgent aspect of the situation. Many farmers have staring them in the face the fact that some of their plant is becoming worn out. Are replacements to be made at the present level of prices? If implement manufacturers with the assistance of a prohibitive tariff are not able to sell at lower terms than the incredible ones they now charge, it is quite evident that they too want their costs drastically reduced. So far, I hope that you will have agreed with me, that a determined effort to reduce costs is an entirely reasonable attitude. And I cannot help feeling that if some of the energy that has been wasted in clamouring for subsidies of one sort or another had been concentrated on this question farmers to-day might have been in a stronger position than they are. But for the fact that the wheat industry with the wool industry keeps, as it were, the Australian pot boiling, we should long ago have been queued up at the Bankruptcy Court, but it is not a pleasant situation.

To come now to the question of costs. One may divide them up into three sorts. Those controllable by the farmer, costs which may be regulated, to a certain extent, by more scienific farming, *e.g.*, fallowing, improved varieties of wheat, &c. There are those costs determined by the fiscal policy of Australia—tariffs, taxation, &c. The burden of these is difficult to compute, but is undoubtedly very heavy now. And there are those costs more or less out of our control, such as the costs of cornsacks, petrol, and interest charges.

How to Reduce Costs.

In what way can a farmer himself reduce his costs? Imagining his farm not so much as a wheat growing business, but as a general business, he can, of course, become more self supporting by extending his sidelines. Sidelines are often no more profitable than wheat, and that it is just as easy and no more pleasant to lose money by breeding pigs, for instance, than by doing anything else. Cows and poultry seem to offer possibilities at the present time; sheep I regard not so much as a sideline, but as a necessary factor of wheat growing. A point to remember, however, is that no sideline can compensate the farmer for growing wheat at a loss.

Crop Rotations.

There is one way, however, in which a farmer has control over his costs. That is in his method of cropping; he can adopt that method of crop rotation which in the opinion of experienced men is most likely to produce more wheat to the acre. I have divided my farm into three areas, and I intend to keep to fallow-wheat-oats rotation. I hope in the future to be able to resist specious appeals to grow more wheat, and not to succumb to the temptation to abandon this rotation if the odds are in favor of a wet season or a higher price for wheat. For what they are worth I give my reasons for this rotation:—

(*a*) Grow more wheat to the acre by confining wheat to fallow.
(*b*) By regarding the oats as of secondary importance, to be put in early and dry if necessary, one can get all one's wheat in at the most favorable time.
(*c*) The oats should in normal years provide valuable reserves of fodder.
(*d*) The farm should be able to support more cows and/or sheep.
(*e*) The oats would improve the value of the land for wheat.

This rotation implies wheat on fallow and nothing else but fallow. We have often been advised to fallow more, and we know that wheat on fallow produces, as a general rule, a better average than wheat on stubble. For my information, I have kept particulars of the amount of wheat produced by each paddock each year. I analysed these figures recently, when I worked out what would have been the difference had I reduced the area cropped by 25 per cent., making the balance all fallow, and basing an estimate of what the crop would have been, on the average actually obtained, off the fallowed area. For instance, in 1925 I had 25 per cent. fallow and 75 per cent. stubble. Had this area been reduced by 25 per cent. and been all fallow; given the same average right through that I obtained off the fallowed area, I should have obtained 25 per cent. more wheat. In 1926 with 48 per cent. fallow and 52 per cent. stubble, a reduction in the total acreage of 25 per cent. would have given approximately the same quantity of wheat. 1927 and 1929 were drought years, and can hardly be brought into this examination. I might point out, however, that in both years the fallow produced wheat, while the stubble was a total failure. In 1930 there was no fallow so far as I was concerned. The only year in which a reduction in the area cropped would have meant a reduction in the total quantity of wheat was in 1928, when for some reason or other the fallow and stubble averaged exactly the same. This, however, is an exception, and on the face of it, it appears as though a reduction in acreage, with wheat only on fallow would mean at least an equal quantity of wheat. With some farmers I am sure it would result in more wheat. In any case it would mean more wheat per acre, which I believe is what we want to achieve.

I have touched briefly on these points—crop rotation and fallowing—because they represent about all that a farmer is able to do in an effort to put his business on a sound basis. And it is little enough. There are few farmers who have not cut their costs to the bone and are now farming as economically as possible. What then can we do? Obviously when we have done everything possible to economise, to practise farming on sound lines, and to keep our creditors at bay, we have to turn our attention to those costs which are imposed on our industry by policy or by legislation. I should like to mention one tangible reduction in costs, and incidentally the only one which has so far come to farmers, and that is the reduction in interest. It is to be hoped that in the near future there will be a still greater reduction, and so ease one of our biggest burdens. It is interesting to note that some implement firms are still unable to see the justice of passing on the reduction which they have obtained themselves to their customers, and still claim 10 per cent. Nothing but an Act of Parliament would make them reduce their 10 per cent., and I am convinced nothing but a little genuine competition will ever make them reduce the prices of their products.

It is perhaps not possible to estimate accurately the burden which the monstrous accumulation of indirect taxation and a prohibitive tariff lays on a bankrupt industry. I remember that some years ago a committee of economists put the effect of the tariff at 10 per cent. of prices. It must be much higher now. [Note.—This committee estimated that if the burden of protection were lifted from the farmer he might hope for another 7d. a bushel. What is it now, plus the indirect taxation?] I do not know what the latest figure is—perhaps 20 per cent. or 25 per cent. When you consider that the total removal of this burden—I am not suggesting that that is practical—would bring a payable price for wheat almost in sight it seems astonishing that so little effort is made to bring about some useful adjustments. Yet it is so. And so far from the upward movement being checked, the position is the reverse. I note, for instance, that a plough part for which I paid 25s. last year is 30s. this year; next year with luck it will be 35s.

This problem—the problem of how to call a halt in his ever-increasing costs—is one of the most important questions a farmer has to face. And I might say, has been for a number of years. We have to try to produce wheat at such a margin of profit that we can pay off some of our arrears and establish a reserve for the future. But if we cannot do this, at least we can aim at keeping our industry going without the dubious varieties of assistance that are usually demanded. It seems incredible that no definite effort has been made to assist one of the basic industries of Australia along the lines of reduced costs. The only efforts so far to assist us have been in the nature of Acts of Parliament, such as the Farmers' Relief Act, to ensure that somehow or other someone kept on growing wheat; and by the Federal bounty.

I am not suggesting that costs can be brought down to the present level of prices, or even that it is desirable to do so. Yet it is beyond all reasonable doubt that much could be done to put the wheat industry on a sound basis, if there were the will to do so. But of that there is, unfortunately, no evidence whatever. However pleasant it may be for the individual farmer to receive a bounty for his wheat, or to dream dreams of an Australian price for wheat, or to take part in agitations for a sales tax on flour or to sow his wheat with subsidised super, his fundamental insolvency remains. If the insolvency of wheat growers was due entirely to the fall in prices, one would have to regard it as an act of God and put up with it. But it is not so. Some years ago an accountant told me that of the hundreds of farmers for whom he compiled income tax returns, only two or three were, from an accountant's point of view, growing wheat at a profit. And this was before the fall in prices.

I have criticised this aspect of the situation, perhaps more mildly than it deserves, because I think that farmers themselves must bear some of the responsibility. Confronted by a problem on which you would think farmers would be unanimous, their energies have been wasted on useless and generally impossible schemes. As an example, let me mention the latest, the proposal to subsidise super. Altogether apart from its merits what probabilities has the scheme of being adopted? Personally I should not like to put much money on it.

So far all that I have said must have been only too painfully obvious, yet unless some sort of action is taken it is quite clear that the situation will drift, creditors, farmers, and manufacturers pinning their hopes to a miraculous return of high prices, comforting themselves in the meanwhile that the corner has been turned, or if it has not, it will be in a few moments.

ORGANISED PROPAGANDA.

There is one question I will put forward. The wheat industry is not a highly organised industry like the sugar industry or the secondary industries. It is essential that it gets public opinion on its side. To do this it must engage in an intensive propaganda. It must educate public opinion, it must try and educate politicians and incidentally it must educate farmers themselves. It should advertise its facts, its figures and its disabilities in the press day after day, in the same way that the sugar industry keeps its affairs before the public. It should publish the results of inquiries into the effect of the tariff, and if necessary, undertake more research in this direction, and it should so keep itself in the public eye and ear, that the authorities are finally compelled, by sheer exhaustion, to give the same amount of consideration to the wheat industry as is given to every little secondary industry which cares to establish itself in Australia.

How is this to be done? First of all, I suggest that all organisations which represent farmers should abandon controversial items in their programmes and concentrate on this question of costs. When we have grown our wheat at a heavy loss, the question of

whether we should pool it or not is irrelevant. The organisation having done this, the farmer should submit to a small levy on his wheat to pay the expenses of the campaign which I have suggested. Incidentally, I should like to see a paid professional organizer in charge. Of course, no doubt, a certain proportion of farmers would not agree to such a levy—would think that their money was being wasted, and would pin their faith to more subsidies and bounties. Like the French nobleman who declared when the old monarchy went bankrupt "When others hold out their hands, I hold out my hat." I can personally see no other way of dealing with the present state of affairs; and the fact that at Ottawa, Australia's tariff policy was advertised as "unchanged," makes action on our part imperative.

For some years wheat growers and other primary producers have faced a period of unprecedented low prices. Both individually and as an industry they have suffered a severe strain. Nor can anyone deny that they have made every effort to cope with an almost impossible situation. They are, however, still selling their products in the world's market, and in one way or another have managed to keep going. It is astonishing that wheat growers, in spite of the almost hopeless conditions under which they have to carry on and the contemptuous disregard of their real needs, have kept going so cheerfu'ly and philosophically. The years 1927 to 1932 have brought droughts, low prices, and increased costs. There are few farmers who, if they could have been told, say in 1926, of what these years were going to mean, would have believed that they could have survived them. Yet it has been done and wheat is being produced, and farms are being managed, more efficiently than before. In other words we are still here.

I cannot help wondering whether our secondary industries, if faced, perhaps not by the full blast of world competition, but by a gentle breeze, would be ruined as quickly as they expect to be. I cannot help thinking that if they met such conditions in the same spirit and with the same fortitude as farmers have met theirs, they would still be there too.

"The authority of a Government can only be maintained by taxes; all taxes must, at last, fall upon agriculture; and agriculture can never flourish except under the protection of justice and moderation."

That statement was made 1,700 years ago. It seems as true to-day as it was then. It should be our aim to spread the truth until it is generally realised and acted upon. I hope, however, that it will not take another 1,700 years.

THE VALUE OF EXPERIMENTAL STATIONS TO SOUTH AUSTRALIA.

[By R. PENGILLY, Alawoona.]

The recent closing down of experimental farms leads one to consider whether or not such a policy is really an economical achievement, or a backward step in these times of progress; when the scientifically minded farmer is the one who is more certain of a return for his labour than one who does not take advantage of available information. The State has been and will continue to be for generations hence, dependent on the primary producers for its wealth and revenue, because the realisation of the world's wheat harvest, and income from other primary products is vital to the government, to administrate the affairs of the State.

Farmers in the past few seasons, through droughts and world depression, have suffered and held out against greater odds than people in the city realise. Droughts reduced the wheat harvest for three successive seasons and when climatic conditions became more favourable, with the end of the succession of droughts, prices slumped to unthought of levels, so that the prospects of speedy recovery appeared pretty hopeless.

On the surface, the apparent losses that occur in connection with the running of experimental farms, seem very heavy, especially when published, are without a doubt, only one side of the question seen from one angle.

One cannot pay much serious attention to this side of the matter without taking into consideration the many other aspects of the matter which need careful thought.

Experimental Farms are first sources of education to the primary producers, on whom the country is dependent, and it is only reasonable to assume that the educated and scientific man is the most efficient man. Efficiency naturally results in better work and great production, and any increase in production, no matter how small, is of benefit to the producer and therefore the State. I have heard it said by some people ''Why not let the farmer do his own experimenting'' but these people do not realise the tremendous amount of work, and costs entailed in carrying out even one separate experiment, much less the number, generally in hand on any Experimental Station. Further, it is only occasionally that an experiment results in an unqualified success, and hundreds of expedients one tried out before the objective in the minds of the experimenters is perhaps achieved. The ''trial and error'' system of procedure is the only method possible with experimentation, and naturally all atempts that fail to reach the desired objective are a direct loss of time and money to the eye of the casual critic.

Such failures however, are far from losses, when the experience gained by the attendants, and knowledge gained on a better method of procedure for the next attempt is considered. It is true that on experiments and trials that prove failures, there is little or no tanglible return, but often the objective when reached after hundreds of false starts, more than repays the cost of previous failures. As an example, the various work to be done in the breeding up of a new variety of wheat at a typical experimental station, from the original selection or crossing of varieties to the distribution of the new variety to producers can be cited.

In the first season, the actual cross between the two parents is made, and the maturation of seed from this cross takes up the first season. The following season these crossbred seeds are sown and at harvest time the process of selection and demonstration of the breeder's skill comes into play. He has to select carefully the most promising types from a host of differing plants and probably only two or three per cent. are retained, and the rest discarded. The third generation is next handled, the seed from the second generation being planted, and a further process of selection of suitable types, carried out before obtaining seed for the fourth year.

In the fourth year this seed is sown in small plots and submitted to field tests, which may result in a small or larger percentage being discarded according to whether the results of the tests are satisfactory or otherwise. In the fifth year, larger plots are sown with the fourth generation seed and further tests and selection take place. It then takes one or two years more of trial and tests before the variety is deemed fixed. The small amount of seed has then to be multiplied in stud plots, and then bulk multiplication plots before sufficient seed is available for distribution to farmers.

Thus it takes from six to ten years or more to develop a new variety of wheat, provided—as is often the case—that the new strains do not have to be rejected at some stage or other before the task is completed. So it may be seen that such an undertaking is beyond the limits of the time and patience of the average farmer, who has dozens of other things to occupy his time, besides taking the ever-present risk of partial or utter failure. Time means money, and the average farmer cannot afford to lose either time or money in hazardous undertakings which may or may not bring in a return.

Experimental farms do not confine their attention to wheat breeding alone or any other selected experiment or trial. As an example, I enumerate some of the experiments being carried out at Roseworthy College:—1. Rotation plots: comparing various rotations of crops. 2. Manure variety plots: trying out nine different manures on wheat. 3. Superphosphate plots: different dressings of superphosphate on wheat. 4. Depth of ploughing tests: different depths of ploughing from 2in. to 12in. 5. Tillage plots: 15 methods of fallowing. 6. Time of seeding plots: wheat sown, May, June, July. 7. Rate of seeding plots: 60lbs. to 100lbs. per acre. 8. Methods of pickling: formalin pickling tests. 9. Pasture top-dressing plots. 10. Lamb breeding experiments, &c. Few people realise the amount of information that is really available from these trials, but the authorities do their best to bring information to the producers, through reports and bulletins. It is the farmer who is to blame if he does not take advantage of these, chief among which is the Bureau as a means of disseminating this information.

Arguments have been put forward urging that numerous and scattered Experimental Farms should be done away with and the work carried out at a central station instead. The necessity for Experimental Farms in typical areas is that the climatic and soil conditions vary so much and naturally agricultural practices and methods differ. Moreover, each typical class of country has its own problems and difficulties to overcome. A tremendous amount of labor is necessary on Experimental Stations because of the hundreds of small jobs which need careful and individual treatment.

I have tried often to convince city people that the farmer must have a useful knowledge of a dozen or more trades in addition to the actual business of working his land and raising crops or stock.

The average farmer is dependent on himself for the execution of a host of jobs, one of which could probably only be done by a city tradesman. Is it fair that a farmer should be denied the right to benefit by the knowledge of men who have been better educated than he in order to work out the scientific experimental work on Experimental Farms? Government Experimental Staions are in charge of men who have had an education fitting for their work, and which has often been unobtainable to the average farmer, and thus farmers should be able to leave the actual experimentation and trials to men and equipment better suited to the work and be content to put to good account the results from the experiments when made available for him.

Finally, the large figures reached by the costs of such Experimental Farms are often cited as being a justification for their abolition, but every ½bush. added to the yield of wheat, every little increase in quality of stock, every method which improves on previous methods, means much more in hard cash to the State, than the cost of running the Experimental Farms which bring about these improvements. An increase of a bushel of wheat per acre on Australia's wheat yield means an addition of £3,000,000 to the nation's income. If the butterfat production of cows can be only improved by 10lbs. per cow per year it would mean an additional income from production of £2,000,000.

Of the 13 most popular wheats in South Australia, seven are Roseworthy wheats. It is reasonable to assume that these wheats are at least half a bushel better in yield than those whose place they have taken, and on this assumption the net profit to South Australia through cultivation of College wheats is approximately £100,000 per annum, which is many times more than the entire expenses of the College, and this results from only one branch of the College activities. That is an example which shows that such institutions deserve their place in the State, as does anything which aids primary producers in the carrying on through the depression.

CO-OPERATION AND THE AGRICULTURAL BUREAU.

[By P. R. Hodge, Secretary Taplan Agricultural Bureau.]

The word "co-operation" is a splendid one and has a power of meaning. It is found in the titles given to some of the greatest organisations in the world, and when applied to any movement whatsoever invariably means success.

Work of Bureau and Department.

A striking example of the power of it is in our Agricultural Bureau system, which is no less than a great co-operative organisation and one of which we should feel proud to be component parts. Who can put forth arguments against this great movement and justify them with any degree of reason? When we think of the wonderful work done by the Department of Agriculture at the various institutions in the State and the knowledge imparted therefrom through the *Journal of Agriculture* and other channels to any one who wishes it, for a nominal charge, there can be no reasonable argument put forth that the Agricultural Bureau is not one of the best friends the primary producer knows.

Help for the New Farmer.

How many men, taking up farming with perhaps little or no previous experience, or going into a district where conditions of farming are entirely different from what they have been used to, have had the Bureau to thank for information which they required. There are many cases of men acquiring farms in a heavy land district when possibly they have always been used to country similar to our own, or *vice versa*. What is the easiest way for such a man to obtain the necessary information? The answer is, to join the nearest Branch of the Bureau and listen to the papers read and discussions following, and the views of not only possibly a neighbor, but several farmers of the district are heard. By doing so, different opinions are obtained, and here the word ''co-operation'' comes in again. When farmers meet together and discuss the various problems and reach a deadlock in connection with the trouble confronting them, further free and expert advice can always be obtained from the Officers of the Department of Agriculture who make a study of such problems.

Individuals Cannot Experiment.

The average farmer has not the time to put into the experimental work to overcome these various difficulties, and here the experimental institutions come to our assistance. These places, on the other hand, are helped considerably by the co-operation of the farmer as, for instance, in the matter of forwarding specimens of diseases found in crops, soil troubles, or animal diseases, &c. This work is usually done through some Branch of the Bureau, whether the person desiring the information is a member or not. In any case, the advice given is always from the Department, and that is ample reason why every farmer should recognise his duty and join some Branch of the Agricultural Bureau.

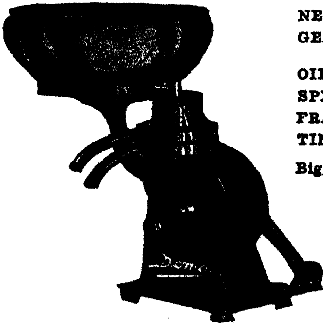
Pass on Your Knowledge.

Even should he be fortunate enough to be sufficiently educated in all branches of his calling to need no further advice, what could be more reasonable and neighborly than

THE NEW MODEL DOMO

AWARDED THREE PRIZES AT THE ROYAL SHOW, ADELAIDE, 1932

ARRIVED ! !



SKIMMING BOWL, semigyroscopic.
BOWL SPINDLE, with improved conveyor.
NECK BEARING, with spiral spring cushion.
GEARING, new Automatic type. No springs or pins to handle.
OIL SUMP protected against milk or water.
SPEED INDICATOR.
FRAME beautifully enamelled, and
TINWARE heavily tinned.

Bigger sizes fitted with BALL-BEARING SPINDLE, eliminating neck bearing and reducing OILING TO ONCE A YEAR.

OFF WAYMOUTH STREET (Opposite "Advertiser")

for him to give the benefit of his knowledge to someone else less fortunate? The local Branch of the Bureau is what the residents make it, and the meetings can be made as attractive as the members care to make them.

I am a firm advocate for co-operation in the working of our farms or any other line of business in which we may be engaged. He is a fortunate mallee farmer who has never found it necessary to borrow from a neigbor, nor had to ask for help with some special job in hand. Pounds can be saved by neighbors co-operating with each other. As, for instance, in the loaning of an implement or by helping each other when laborers are not available, possibly for such jobs as chaffcutting or other two-men jobs, much of the labor difficulty can be overcome.

In the matter of drift and other bounadry fence troubles, the co-operation of neighbors concerned will save endless arguments and considerable ill-feeling, as a seemingly impossible job is made to look simple by discussing the matter and getting to work as one man.

Co-operation between employer and employee is a splendid thing, and makes the work much more interesting and very often more profitable to all concerned. Unfortunately, however, too many men nowadays apparently think only of the remunerative side of the job, and co-operation is foreign to them.

SOME OBSERVATIONS ON BUREAU MEETINGS.

[By A. N. McKenzie, Taplan.]

I have long felt that many Bureau Branches fall short of their aims. This is chiefly due to a general lack of interest and to a want of knowledge of the facilities which are at the service of Bureau members. Generally speaking, Branches are showing signs of a revival of interest, and these suggestions are put forward to cultivate that interest.

Membership.

Every farmer in a district should be a member of the local Branch of the Bureau. While this is not practicable to that extent we fall far short of it, and we might easily increase membership if every member were to talk about the Branch, its meetings, and the advantages of membership, and so persuade others to join. The individual has the help of his fellow members, and the experience of the Departmental Officers as well as the results of scientific investigation at his call. Then the district gains greatly if all the farmers are working in accord, and so improving their farms and boosting the district.

When new members have been obtained it then falls on the Branch to retain their interest and membership. This can only be done by making the meetings interesting, instructive, and sociable. The following few suggestions, I believe, will help to obtain that interest in our meetings:—

Papers and Lectures.—The reading of papers by members is a very good idea if it provokes discussion afterwards, but that does not carry us far enough. To complete these we should have lectures by the Departmental Officers, so that some finanlity might be reached upon important questions. However, before we can expect the Officers to visit us we must show them that we are a live and interested Branch.

Use of Facilities.—As a body we should make more use of the facilities offered to us. We seldom carry our problems to the experts for explanation or solution, yet we pay them for that purpose. How few of us know what is being done at the Waite Research Institute, yet there we have a most up-to-date institution, and one which is visited by the leading scientists of the world when in Australia. There we have specialists at work in their various departments solving problems for the primary producer, who very often knows nothing of it because he does not take the *Journal* or the pamphlets issued by the Department of Agriculture. We should keep in touch with these institutions and with the results from Departmental experimental work. An outstanding example of this is the work with the pastures at the Kybybolite Farm.

Items of Interest.—Members can create a great deal of interest and enthusiasm by introducing items of interest such as experiments and experiences in pickling, sowing, cultivation, &c., and also by bringing along their problems and mistakes. If a farmer does make a mistake he should ensure that no one else falls into the same error.

Exhibit Night.—I noticed a report of a Branch which held an exhibit night on which members brought along various gadgets and makeshifts which they had made themselves. This appeals as a good idea, both to create interest and to pass on ideas gained during the year.

Harvest Reports.—In many Branches after harvest a night is set apart for harvest reports. During this evening farmers give reports on their best and worst crops, and if possible, give reasons for their success or failure. Farmers tell each other these facts outside, so why not make them useful to everyone by stating them inside at the meeting?

Homestead Meetings and Tour of the District.—By far the most effective meeting is the homestead meeting where the lecture or paper is accompanied by a demonstration. These need not be confined to the visits of the Officers of the Department, but could be held whenever a member wishes to give a paper on something which he can demonstrate on his own or someone else's farm. A variation of this is a tour through the district when the crops are standing and a discussion held on the merits of crops, method, &c.

Crop Competitions.—Every Bureau should foster crop competitions. These are undoubtedly a good thing both for the farmer concerned and the district. One notices that places which take their Crop Competitions seriously get much more publicity than those which do not. This has an undoubted influence on the district, and has an effect on the finance of the district in respect to confidence, &c.

DEVELOPMENT OF MALLEE FARMS.

[By F. MASTERS, Roberts and Verran.]

(*Kimba Conference, October 3rd, 1932.*)

Of the millions of acres of arable land on Eyre Peninsula, probably not more than one-sixth has yet come into production, and therefore there is much developmental work to be done, and consnderation of factors affecting the development should prove of interest and profit.

Much of this new land still remains upon occupied farms, while a smaller portion is mallee land still untouched, awaiting brains, brawn, and energy.

The first essential is capital, and here usually the new settler is handicapped. Had he sufficient he could purchase a cleared farm and avoid the risks of pioneering work. Generally speaking, the settler in the mallee is one with limited finance, and this fact alone calls for adoption of shrewd planning and management, as he finds it necessary to refrain from expenditure. Hence, the subjugation of most mallee farms becomes a long drawn out process. Finance procurable is from the State Bank under Advances to Settlers for sheds and tanks, and clearing and fencing purposes, or alternately in regard to the latter through the local district council if there be one in the locality. Of course, prior to that the settler must have either stock and plant, or money sufficient to purchase, and the better his equipment the greater likelihood of success. I have known cases where settlers have started without capital, stock, or plant, and eventually made good, but here it is a case of individual judgment, management, and tenacity, which it indeed also true in any case, as we find on the other hand failure coming to men with capital, and good stock, plant, and equipment. After all, mallee farming is a profession, and cannot be learnt except by long study and experience, and to place city bred men on these farms without proper experienced control would be sheer madness. Many a would-be settler has failed because of inexperience, and lacking the power to adjust himself rightly to his new environment, and profit from experienced neighbors, while it must be said that those of this class, having capacity of adjustment, and by using the advice of experienced men, have successfully developed a mallee farm. The vocation is full of problems; circumstances vary with the seasons, and differing amount of finance, as well as varying prices and marketing difficulties, call for the highest resource and initiative, so that mallee farming demands the highest of these faculties to succeed.

Clearing.—The farmer has to determine the area possible, whether tractor, horses, or bullocks will be employed for the purpose, and have it done in a suitable time ready to burn in the season. A good burn is the desideratum, and it should be rolled or logged sufficiently early to allow the timber to dry. This will avoid undue expense of stick picking, &c., and make for a better crop. Patchy burns mean patchy crops. From year to year, until the farm is cleared, this process has to continue in areas according to judgment.

Cropping follows, and much depends upon cultural methods, time of seeding, varieties of wheat, oats, and barley sown. Also treatment of seed to prevent bunt, smut, &c., and the method to be adopted. It is easy to err and sow too early or too late, select an unsuitable wheat—say late wheats for early districts, and so on with oats and barley. Errors of judgment are costly and should be avoided.

Plant and machinery make or mar success, likewise their economical use. Here the potent factor is finance, as requirements frequently have to be cut down to an uneconomical basis. For small areas it is questionable whether a full kit of implements and machinery should be purchased. Better make some arrangements with others similarly situated than overload in commitments on machinery. If this cannot be done the settler works at a disadvantage. The essential point with implements and machinery is to have them worked at full capacity, and if this can be secured means a step onward to success.

Labor dovetails in with machinery, and some few years ago the premium on labor was such that farmers were forced to displace it as much as possible by machinery. Even now with the unemployment existing, we are forced to follow those lines. One man can handle a large implement or machine as effectively as a small one. Family labor has frequently meant the difference between success and failure, but this does not mean that labor had not been remunerated. It may have been delayed, but eventually paid in assisting starting the family elsewhere. To-day many farmers cannot employ owing to drought and other encumbrances. Better than unemployment relief, to spend that money in assisting in developing mallee farms, and incidentally, training men for primary wealth production.

Water provision must be made early and from time to time as required, by dams and tanks, unless the settler is fortunate enough to have water laid on. The latter is preferable, as being permanent and also cheaper, as well as not absorbing time, labor, and money in the earlier stages when clearing and cropping are most necessary. I rather incline to the opinion that the Government should provide the reticulation of every farm in national and individual interest.

Stock raising, as soon as water supplies are assured, should be practised. It necessitates fencing and yard provision, &c., but no expenditure is more warranted in view of the returns likely. Mistakes are frequently made by fencing the whole of a scrub block right away, as such fencing earns nothing and is menaced by fire. Refrain from such useless expenditure. In the earlier stages, and, indeed, always understock. Feed should be sown for sheep, cattle, and pigs, and stores of hay and ensilage placed by against lean times. Relatively the labor costs of livestock to returns are lowest of all farm operations. Depreciation should not take place, but stock are notable for their appreciation in values provided food and water are plentiful, and become the anchor of a mallee farm. The selection of the flock should be Merino as a base, and crossbred for production of fat lambs for export.

The fat lamb business means producing them in the season when feed is plentiful and turning them off before supplies diminish to the advantage of the ewes for a succeeding crop of lambs. If kept for wool only care must be taken to grow the progeny, and less can be carried.

Dairy cattle, of milk-producing capacity, should be kept, and each cow's milk weighed and tested regularly. Thus a high producing herd can be built up with certainty, where to-day the haphazard methods followed diminish the returns and no profit results. To grade up a herd I commend the Government bull subsidy scheme as making it possible and potent.

Pigs should have their place on every farm, utilising waste and turning grain into greater profit. Even with price of bacon at 4d. and foodstuffs all purchased it has been proved that a profit of 1½d. per lb. can be made. With farm-grown grain the results should be greater, when the saving in bags and freight is considered. Freight on the hoof is cheaper than in bags for such grain, and this applies also to cattle and sheep in connection with foodstuffs fed.

Poultry likewise assist in the development of our farms by converting grain to other products. The sooner the new settler can devote his attention to these sidelines the safer the basis of his operations.

Efficiency should be the keynote of all operations as promoting lower working costs. It is essential that the costs of production be reduced wherever possible through this factor. Prices of all our produce have receded considerably, but prices of production have not anything like the same ratio. It is our business to see that they do, so far as we are able. The running of our tractors on charcoal gas promises toward this end, but their original cost still remains too high. Likewise all machinery and farm requisites, cornsacks, &c., are relatively too high. These are factors which operate outside and over which we have little power, but we have the right to register our emphatic protest and demand efficiency in manufacture and distribution. Machinery duplicates are too costly. Recently a bottom comb and steel riveted on mouthpiece of my chaffcutter cost me 17s. 6d. (about three pounds of cast iron, and a small hardened plate altogether), a hide is purchased at from 3d. to 4d. per lb., but my leather costs me 2s. 9d. per lb. Can the difference be defended?

These are illustrations of what is going on and we have a right to ask for investigations as to whether manufacture is efficient and charges justifiable seeing the mallee farmer has to reduce his costs of production. It is imperative that each mallee farm should continue to develope and provide export trade as well as local, but this can only be done on right lines demanding our best judgment, resource, intiative and energy. We have made many mistakes in the past and experience and expert advice from the Agricultural Department should largely prevent these if applied. As to tariff and manufacturing costs, their effect should be determined and adjusted in our interests and the interests of the State.

The development of our mallee farms to the fullest extent is, I believe, the economic salvation of the individual and the State, and suggestions that they should carry 1 sheep to the acre without reducing the cropping area is a worthy ideal given by Professor Perkins.

Marketing our produce to best advantage is deserving of our best attention. After all the expenditure of time, thought, and money producing to the utmost to have the value reduced by faulty methods of marketing, excessive freight as well as other charges and profits are militating against proper development of mallee areas.

The direct shipment from Eyre's Peninsula of its products to the place of sale is of first importance. In this connection also direct shipment of all our requirements would reduce their cost. The centralisation of trade in Adelaide of our produce and requirements costs Eyre's Peninsula a huge sum annually.

Whether alterations in our methods of disposing of our production, such as bulk-handling of wheat, developing the infertile egg sales and dealing with them and all sidelines here are matters worthy of discussion. What it means to have manufacture of super. here is evidenced by a reduction of about 10s. per ton on that article all round. Marketing on a co-operative basis appeals strongly to me, but I realise that to be most effective it must be hundred per cent. business. Should not the farming industry control its methods of marketing and a majority decide those methods?

DAIRYING IN THIS DISTRICT (KIMBA).

[By A. Jericho, Balumbah.]

(*Kimba Conference, October 3rd,* 1932.)

Some years ago I set myself the task of writing on a similar subject, and among other things, stated that where a man had all his paddocks sheep-proof fenced, it was not profitable to keep more cows than were required to supply milk and butter for the household. At that time wool was realising £40 a bale and wheat 15s. to 16s. a bag; but since wheat and wool are back to normal, we must look to other sources of revenue to make up the deficiency in capital we have to handle throughout the year.

Dairying comes next to wheat and wool, and the available labor will play an important part in placing the credit balance on the right side of the ledger. I do not advocate any particular breed of cow for this district, suffice to say we have men in South Australia specialising in the different breeds, and some of them possess stock that would not be a disgrace in any part of the world. These men have spent a considerable amount of money in building up their herds, and are entitled to their reward; but to pay them for their enterprise is above the average farmer's pocket, therefore, we must look to other ways of improving our herds that are within our reach.

I advocate line-breeding. Ascertain which is the best cow in the yard, and make her the foundation cow of the herd to be. To improve some of the herds in this district probably three different sires would be wanted in the one year; because the herd consists of so many different types of cows which also possess so many different qualities. It is not a life's work to get a line of cows. In 1926 I purchased a heifer calf, and to-day, six years later, I have seven cows and heifers from that one heifer. A farmer could gradually turn out those lines he does not wish to follow up, and eventually have the one line in his herd.

Having accomplished this, it is an easy problem to purchase a bull to improve the herd. If unable to purchase a bull, always try and secure the service of the best bull in the district, but do not expect it for nothing, because a good sire costs money, and if the owner does not get full term out of him he is going to lose heavily. A scrub bull is allowed to roam about until he gets savage or develops some other vice, and is then turned into beef, and the owner gets full value. Having a fixed object in view on breeding the farmer must pay a little attention to the growing stock. The calf should be taken away from its mother as soon as convenient and artificially fed on good milk for a week after that. Gradually add a little separator milk and scalded linseed meal. If the feeding vessels are kept scrupulously clean, failures will be rare.

After a week get the calf on to green feed or chaff and after a month or so it can be trained to walk out with the cows. It is a good practice to allow calves and young heifers to come home every night and be shut in a separate yard during the milking. When the heifers show signs of freshening, rope and handle them. After a few handlings they become very quiet. When near calving, watch them closely, and when the milk flow appears, milk regularly whether she has calved or not. Even with this attention you will find the heifer restless after calving when being milked; but not one in ten will kick viciously and by gentle and careful handling—usually a couple of days after calving—she will settle down. Wet milking causes about 80 per cent. of the restless "kicking" cows. It is essential to watch all the cows before calving and milk as soon as the flow starts. Always feed the best of everything. I always turn my cows into a different paddock of green feed (when available) at night to where they have been through the day, and encourage them to drink twice a day. About twice a week feed phosphate lick with some dry feed in a nose bag. Finally, all work with the cows should be as regular as possible.

In reply to a question, Mr. H. B. Barlow (Chief Dairy Instructor) stated the pollard could be used successfully to replace linseed meal. Calves should be brought on to linseed meal gradually, as otherwise it was likely to scour them. He disagreed with Mr. Jericho in advocating milking before calving. This should be done only when the heifer or cow appeared to be abnormally in pain and then to a limited extent, merely to ease the milk supply. Milking before calving was dangerous, as the cow was likely to develop milk fever by this practice. Again, cows should always have access to drinking water, as the more water they drank the greater would be the production of milk.

FARM RECORDS.

[By F. Galloway, Kimba.]

(*Kimba Conference, October 3rd,* 1932.)

I have lived amongst primary producers, principally farmers and fruitgrowers, for the greater part of the past 12 years, and one of the first things that always comes to my mind, which, being an accountant, probably may be in a more or less biased state, is the seeming lack of attention paid to that side of their business which I regard as of the utmost importance. I refer to the accountancy or, to put it in a more applicable way, "records" side of any primary producer's business.

The records that I propose to touch on require no more than common sense, the ability to read and write, and a passing knowledge of figures. The records, after all, are not for the Income Tax Commissioner, the banker, or for anyone else, but yourself only, and so long as all the information you desire is readily available, the simpler the record the better it is.

Naturally to a farmer the paramount record is that of your principal product, grain, but the mere fact of being able to say that "I have had an average of 1,500 bags of wheat for the past 10 years," amounts to nothing at all. What you want to be able to say is, "Ten years ago I grew 1,500 bags of wheat, and now I am growing 2,500 bags of wheat off the same area," and one of the ways which will help you to be able to say this is to keep a suitable book, not just a paper-covered note book, but, say, a journal, with stiff covers, which is obtainable at most stores for a few shillings, and in that book set aside sections of say, 10 or 12 pages for each of the items which it is intended to record, so that each particular section is kept together from year to year, and not mixed up in a few pages, and eventually neglected altogether because it is not possible to make head nor tail of the thing.

Each farmer has his particular lines of which records are necessary, but to cover the ordinary case I would suggest the following division as being sufficient:—1. Grain, including wheat, oats, fallow, super, stubble, &c. 2. Hay and fodder. 3. Horses. 4. Machinery (farming plant). 5. Tractors and fuel. 6. Motor cars and truck. 7. Sheep, wool, and lambs. 8. Cattle, pigs, poultry, &c. 9. Weather. 10. Income. 11. Expenditure. 12. Budget.

Grain.—Keep record of total area sown each year, class of ground, *i.e.*, fallow, stubble, grass, &c., and area of each. Time of seeeding, amount of seed and super per acre, time of fallowing and number of times worked over, time reaped and result of crop, &c., &c., showing result of crop first as total amount and then show the average per acre off each class of ground and finally the general average. At one side of page you should leave a space for notes and there write down (do not keep it in your head) your impressions as to the cause of the success or failure of the crops. Such things to be noted would be:—"Frosts third week May," "Season opened June 5th," etc. Write these records down as soon as the information is available.

Hay and Fodder.—Keep a record of hay and fodder harvested and used. Note areas from which it was taken. Note down the year's price of hay and any other relative information which may be of use.

Horses.—Keep a record of all horses purchased, showing dates, prices, &c. Note when foals are dropped and note all sales and prices realised. This record will be of interest and show exactly where you stand with regard to your horses and what they are worth to you.

Machinery.—Keep record of each machine and show date purchased, approximate area covered each year, cost (if on hire-purchase, allow for interest), cost of repairs and parts, &c. Suitability for wet or dry years and any other notes.

Tractors and Fuel.—Keep a record of cost, repairs, and replacements, cost of fuel and area of ground covered. Work out cost per acre of each class of work. This record is essential to enable you to estimate your anticipated and probable expenditure. Records of actual work and cost are valuable for comparative purposes, but keep them in the book. Do not work it out in your head or on a scrap of paper. A carefully kept record over a period of years may alter your ideas on the advisability of tractor farming, either for or against it.

Motor Car and Truck.—Keep a record or the mileage and costs for fuel, oil, tyres, and repairs, &c., of your truck and car. This will enable you to control your expenditure on these items, which can easily account for a great deal of money if not closely watched. If the car is proving too expensive for the amount of money you have available to run it, then run it less. If the truck is too expensive use the horses more.

Sheep, &c.—Keep a record of dates and prices of flocks purchased, number of natural increase, weights and average of clips, prices realised for wool and lambs, and annual profit derived from the sheep. From this record you will gain information of value in the purchasing of further lines, and will be able generally to know exactly where you stand in this probably most important adjunct of farming in these areas.

Cattle, Pigs, and Poultry.—Keep records of number of each class of stock on hand at the beginning of the year, records of purchases, natural increase, sales, &c., during the year. This record can be easily kept by ruling several columns, and will be valuable to you in selecting the most profitable side lines for your concentration.

Weather.—This record is important. Keep record of rainfall for each month and yearly total, and work out averages over a period of years. At side of page have a space to record any special features, such as length of dry spells, storms, &c. This record will be used in conjunction with several others, but mainly the grain record. Well-kept weather records often mean an appreciable premium to you when effecting a sale of your property.

Income.—Keep a complete record of your income from all sources throughout the year. Show the income from each section of your activities separately, with the prices realised per unit, as a comparison will not be effective unless this detail is clear. The principal items would be:—Proceeds of grain, &c., fodder, stock sold, sheep and wool, dairy produce, and sundries.

For convenience it will probably be necessary to keep a page aside for use during the year on which to note down the income as received. Treat butter and eggs, &c., given to storekeeper in exchange for stores as income. At the end of year put the totals of each item on to the ruled record page for comparison with other years. This record is for yourself only, and not for the before-mentioned Income Tax Commissioner or your banker, so be careful to keep it very accurate. It is very important for you to know exactly what your gross income is, and from what sources you receive it. If one source shows an increase on previous years it is probably satisfactory, but if a decrease is shown, then you can look around for a cause, and if it is in your power you can take steps to prevent a recurrence.

Expenditure.—This probably, to my mind, is the most important of all sections of which accurate records must be kept. If expenditure is not controlled it always creeps ahead of income and the resultant period of depression quickly follows, and there is nothing in this world harder than working off deficits. There is no necessity to keep a complete set of double-entry books, but you should keep a record in columnar form of expenditure on different sections of your farm. This record can be compared with those of income, and you can adjust your affairs accordingly. The main columns you will require for this record will be as follows:—

Direct farming costs: Super, fuel, wages, sacks, twine, oil, repairs, &c., &c.

Other costs: Interest, &c., household and living expenses, motor car, pleasure and personal expenditure, subscriptions, &c.

Capital expenditure: Cost of machinery, &c., purchase of stock, &c.

The Budget.—This will be completed from the information supplied in the various sections of your book and is of great aid to you in determining exactly what you can do for the coming year and not what you would like to do.

To prepare your budget recourse will be made to the records on which I have already spoken, but the principal ones to deal with at first are those appertaining to income and expenditure. After completing your work you can finalise these two records and ascertain exactly how you have fared financially for the year, and will know what money you have in hand with which to carry on for the next year. Having arrived at a starting point, we continue with the budget and decide our farming operations for the year. That is, areas of crop to be sown, classes of crop, varieties of seed, fallow, stubble, grassland, &c., &c., and also proposed holding of stock and sheep and any other lines on which you anticipate concentrating during the year. You will use the records kept to help you in this, and will be guided by past experience and results, and thus arrive at the best thing to do.

Now, having determined what money you have and what you want to do, set the two down and work out what it will cost you to carry out your programme. Do not guess. Write out every conceivable possible expenditure that can crop up and make liberal allowances if possible for contingencies. Apart from the actual cost of material and labor to work out your programme, you must provide for your living and that

ROSEWORTHY AGRICULTURAL COLLEGE.

LIVESTOCK FOR SALE.

During the next few weeks the College can offer for sale the following animals from their well-known flocks:—

Berkshire Boars, from 8 weeks to 8 months old.
Berkshire Sows, from 8 weeks to 8 months old.
Berkshire-Tamworth Crossbred Sows.
Jersey Bulls and Bull-calves, from Tested Herd-book Cows.
White Indian Runner Drakes and Ducks.
White Leghorn Roosters.
Black Orpington Roosters.

— **FULL PARTICULARS FROM THE PRINCIPAL.** —

of your men, and all such items as replacement of plant, possible repairs, purchase of stock, horses, sheep, &c., &c. You must provide for your personal expenses, running the car, entertainment, taxes, rents, interest, and a host of items, but make sure all possible expenditure is included for the coming year. Now you know what cash you have to start with, and can proceed to estimate what income will be received by you during the year from all sources, but principally from sale of produce, stock, hay, sheep, &c. Try and make the estimate as near as you can, but always err on the conservative side. It is safe play to be pessimistic about income, and rather the reverse about expenditure.

If on comparing your estimated expenditure with your cash in hand and estimated revenue, you find that the latter is the smaller, then you must start off and modify your plans and make cuts here and there, until you can see the two sides balance. Of course, you can sometimes make the two balance by borrowing money to supplement your income, but always hesitate to borrow, think twice and even more, because it costs money to borrow money and it must be paid back. Try not to borrow, except for capital improvements which are calculated to return money to you or save you expenditure, or increase the income-producing capacity of your farm. Having managed to balance the two sides of your budget, and arrived at your programme, you are in a position to know exactly where you stand and what you can safely do; but, remember, that having gone to the trouble of working all this out, you must keep to your budget, otherwise trouble will come, and something extra has to be done to overcome it.

If a contingency arises necessitating a departure from one item of your proposed expenditure, then compensate for it by cutting down some other item or adding a balancing amount to the revenue side of your budget.

STARTING ON A VIRGIN SCRUB BLOCK.

[By G. W. Cant, Kelly.]

(*Kimba Conference, October 3rd,* 1932.)

Unfortunately for this State, which depends more on primary production than any other State in the Commonwealth, we have had in the past too many persons who have taken up land for the purpose of speculation. These so-called farmers who, apart from putting up temporary improvements, work the land with the idea of getting the most out of it and then selling it at a profit in boom periods, leaving the unfortunate purchaser to find out that not only are the improvements temporary, but he has bought a wheat sick farm. What is needed is the type of settler who is going to design, improve, and work his farm with the idea of making it a home for himself and his family for generations. This man will use his brains in connection with the clearing, fencing, subdividing, and working of the farm, and each phase of his labor will make it a more valuable property. The selection of a site for the homestead should be the first move. This should be built in a position that will allow the quickest and simplest working of the holding. The lay of the land and fertility of the soil should be well considered before this is done, always remembering that the home and buildings should be in a position that will allow of good drainage and sanitary precautions.

A house in a low, damp locality, or in too close proximity to stables, pigsties, and such like is not a suitable place to rear a family and live for a lifetime.

The clearing of the land is a very debatable question. My experience is the heavier the timber the less the risk in clearing large quantities, as lighter timbered country has more roots, hence the risk is greater (in the event of light crop, which means poor stubble burns) of the land growing back to timber.

Crops grown on new land in the heavy timbered parts of this district depend wholly and solely on the amount of rain that falls during the growing period. In a wet season 20bush. or even 30bush. on land simply ploughed and drilled are quite possible; in a dry season a total failure is almost assured, whereas further south, where the timber and soil are lighter, it is better to clear the land in smaller quantities and fallow all that is to be cropped.

Crops on land of this nature and sown on fallow last season yielded 6 bags per acre, whereas new land adjoining sown without fallow yielded 6bush. Heavily timbered country, while perhaps being a little more expensive to clear in the first instance, can be worked with less plant and labor during the initial stages than the lighter country, so the amount of land to be cleared yearly depends solely on the class of timber, soil, and capital available. Don't clear more than can be handled. Too many farms have been spoilt with trying to clear too much.

Timber is of incalcuable value for shelter and shade for stock, and in the clearing of the farm in the first place farmers would be well advised to think before they cut down certain patches or leave others to be a permanent nuisance. A good reserve of timber around the homestead is most essential.

One of the most important and necessary things to have on a farm is a convenient and ample supply of water, and the farmer who is able to erect the means of raising and conveying it in sufficient quantities to places where it will be needed for stock, house, and garden is a fortunate man, and has added greatly to the value of his home.

Machinery should be chosen carefully, consideration being given to the best type for the job, and the type that will have a fair life. The farmer that spends much time at sales looking for a cheap implement generally finds himself with something that has seen its best days, and has to spend money on repairs right from the start.

Farmers who can manage to start with new implements of a good type are the best off in the long run. They must realise, however, that these implements must be well housed when not in use, and that time given in a good overhaul and clean up after use is well employed. A £200 harvester is an expensive fowl roost.

If horses are to be used as a means of power in working the farm, the farmer should realise that he will save money by buying good class animals in the first place. If this is done, and he breeds systematically, he will eventually own a well balanced team.

Remember that a useless horse eats just as much as a good one, and struggling along with an indifferent team is worth considerably more than the difference between a team of horses and a team of scrags. Lack of power means bad farming, and often a bad temper. Again, the farmer who spends money in securing good horses and does not follow it up with providing good stabling and feeding, is actually wasting some of the money he has already invested. Assets in the shape of livestock deteriorate rapidly if not looked after thoroughly.

Most farmers keep a cow or two, some go in for it more extensively as a side line, but I don't think there is any branch of farming that has been more abused in the past than this. In order to get the best out of this department of farming and value for the time and money expended, it is necessary to secure good cows of a breed suitable for the district and feed available. Here, again, you must help the cow to give milk and butter by providing suitable foodstuffs for its production. No sensible farmer will run his car without oil, but dairy herds are often expected to run without the suitable foodstuffs to make them function properly. A good dairy herd can be soon built up from a good foundation, but it takes many years to produce payable types from mongrels.

Before starting a sheep flock it will be well to decide on the type that will pay best on the average in the district. If you have a heavy growth of feed on your land and need your sheep to run constantly on the fallow to keep the weeds down, it is not feasible that you should expect to produce a high quality, clean Merino fleece that will bring top price in the wool market and it may be advisable to go in for a flock that will produce a good type of lamb for early sale or export. In starting this most important side line on the farm, after deciding your particular breed, procure the nucleus of your flock from some reliable breeder.

Poultry, in common with cows and horses, must be housed and fed properly, have ample run, and kept free from vermin. Taking into consideration the initial outlay and the small amount of work involved, the poultry run, to my mind, is the best paying side line on the average farm.

In order to work the farm economically it is well to remember that repairs will be needed to plant and machinery, and that if you have a convenient workshop and suitable tools you can do a lot of these repairs yourself, and so save quite a lot of time and money. This is a department that calls for careful thought and judicious purchasing. Do not spend money on expensive tools that you are not capable of handling.

No farmer can do all that he would like in laying out the various departments of his farm, but he should do his utmost to avoid makeshifts. It is better to do without some article for a time than to buy a poor substitute that will have to be scrapped before it returns its value.

Do not change your ideas and principles because there is a temporary fall in the price of any commodity, but remember that it is the income on the average that matters, and not the top price you get in any one year.

Finally, having set your farm out and established the various departments to the best of your ability, remember that it will be of little use if you try and farm more than your plant will allow to work properly.

WHY FALLOW AND ROTATION CROPPING?

[By Mr. J. F. Heylen, Pygery.]

(*Central Eyre's Peninsula (Wudinna), October 5th,* 1932.)

In districts with limited or low average annual rainfall and severe spring weather it is essential to conserve moisture to withstand these climatic conditions, and this is best and most economically done by early winter fallowing and subsequent workings of the soil to check evaporation during spring and summer. When land is fallowed in this way, the added soil moisture assists bacterial action to such an extent that approximately 60lbs. of nitrogen per acre will be stored in the soil for the next crop, and practically all of this nitrogen will be taken from the atmosphere. Therefore, this is certainly the most economical way of purchasing nitrates for our soils.

The third factor in favor of this method of cereal growing upon fallow is the assistance that the cleaning of the land of weeds and the added fertility gives to the suppression of takeall, which in the last few years has developed rapidly. Bare fallow taken in conjunction with systematic growing of oat crops and the burning of grass or stubbles upon the soil will effectively and definitely check takeall.

Allied to these three factors is the growing of oat crops after wheat grown upon the fallow. A very profitable crop of oats can be grown in this way, provided an early oat be sown. Therefore, if the previous fallow has been kept free from weeds, a very light working will produce a heavy crop of oats and two profitable crops to the one ploughing.

Now we come to a bone of contention among farmers, many of whom believe that fallowing entails more work annually than autumn working of the soil. This idea is quite erroneous, as by ploughing or fallowing in winter the soil is in better condition for this heavy initial working in the great majorty of cases. Also, the farmer is not so pressed for time, and can wait for rain, and therefore can do the heavy work when conditions are most favorable. Again, during early spring all stumps can be picked from the land, and the following autumn the crop can be sown upon this prepared land much more economically than upon autumn land that has to be broken up. However, concluding this, let me also point out the added advantage gained in being in the position with fallow prepared, to sow at the time the grower feels is the most suited for a good germination of his crop.

The most important reason why fallow and rotation cropping are desirable must be looked at from a business and financial aspect. The system is the road to a greater average yield, both in wheat and oats; also a greater carrying capacity of livestock upon the farm, extra income and less expenditure.

PRACTICAL BREEDING OF DRAUGHT HORSES.

[By Mr. A. J. SHEPHERDSON, Wudinna.]

(*Central Eyre's Peninsula (Wudinna), October 5th.*)

There is scarcely a farmer to-day who is not in need of a certain number of draught horses. A few years ago a young draught could be purchased at from £15 to £25, according to size and quality. At the present time horses of the same age are selling at £30 and up to £40, and the farmer who continued breeding throughout the slump period is now reaping the reward he richly deserves. A few years ago there was a definite swing away from horses to tractors and motor trucks. Farmers to-day are alive to the fact that horses, after all, are indispensable, and certainly much more economical in the working of the farm than are tractors; hence, the demand throughout the State that caused the present high prices.

Farmers are now naturally turning their thoughts to the breeding of the horses which they realise they will need in the future. The slump in this industry has caused a great loss to Australia, but was not due entirely to the advent of the tractor, but also to the lean seasons through which the State has passed during late years, which have had a marked influence in retarding the growth of this industry. With only a very limited supply of horse feed on hand (in some instances bought through drought relief) only the bare number necessary for the efficient working of the farm was deemed sufficient stock to feed. To-day there is ample feed held in reserve on most farms, but with the wetter seasons it is found necessary to have a stronger plant to contend with the bulkier growth of weeds and heavier workings caused by such seasons.

The best and cheapest method of replacing aged and worn horses is by breeding young stock, always providing you are a successful breeder. To stint eight or nine mares to a travelling stallion and get only one foal does not give you that qualification. This may be partly the fault of the horse and to a certain degree due to mismanagement. If you are an unsuccessful breeder, try to ascertain just what is the reason for it; you cannot afford to pay service fees and waste much time by not getting results. It is possible that the mares are not in a suitable condition for breeding. If they are working hard and long hours daily, and are possibly low in condition, it is much better not to bother with them until late spring. Then turn them out where there is good, green picking, and when they have improved their condition, you will find them much easier to get in foal.

When mares have been served, they should not be put to work immediately afterwards, nor should they be left in the yard amongst the other horses, but should be put in a vacant stall or a small paddock where there is no danger of them being molested. Never use a stallion which you have reason to believe is being drugged. You cannot expect to get a satisfactory percentage from such an animal, and it is feasible to believe that stock so obtained cannot have the vigorous, healthy constitution of those obtained under natural conditions. If you are prepared to put up with the bother of his attention and have sufficient mares to warrant keeping a stallion of your own, you will get far more satisfactory results by doing so. He should be put to work on the farm and broken to work in the dray, particularly in mallee districts, where a good dray horse is so essential for stump picking and many odd jobs. By working the stallion you keep him healthy, he is not likely to get foundered from over-feeding or break out in sores on his legs, and most important, he will be found to be much more reliable as a healthy foalgetting sire.

When the stallion is being used for stud purposes, he should always be taken out with a bridle, never with winkers. Apart from the danger of his getting kicked with winkers on, he will quickly realise the difference between the two and act accordingly. If he is never used for stud purposes, winkers make him a much safer animal when working in the team.

It is never advisable to lose sight of the fact that quality counts for much in horse breeding. Do not, for the sake of a few pounds, be tempted to buy an animal of inferior class. Always remember this animal is one of the foundation stones on which you wish to build your future team. Use common sense when purchasing mares for stud purposes, always remembering that like begets like; consequently, you cannot expect to breed a shapely filly from a flat-ribbed, bull-necked half bred draught mare you may have in your stable.

THE CLYDESDALE.

The ideal for which we should endeavor to breed or in the first instance to buy, is—firstly, a mare possessed of an even temperament, docile, and tractable; secondly, to be well ribbed up on a roomy barrel, and possessing nice flat bones, and fine silky hair. Hair denotes quality, and while coarse matted hair on the legs may be an indication of strength, it also shows a decided lack of breeding of the type which is accepted as the best for farm work in Australia, and that is the Clydesdale, and to which my remarks refer.

The Clydesdales of to-day are of a type quite different from those bred several years ago, and in my opinion the change is for the worse. The present type is much lighter in the bone than his predecessor, stands back on his fetlocks and pasterns to a marked degree, which we are told allows him to travel on hard roads with less likelihood of injury to his legs. While I admit that a certain amount of freedom may be advantageous, it has been developed to such a degree in this modern animal as to apparently constitute a weakness.

Care of the Mare and Foal.—It is not a good practice to work a mare which is rearing a foal; it is not fair to the foal nor the mother, and in most cases is injurious to both. Give the foals every opportunity from infancy to make growth and development will rapidly follow if the mother receives ample feed and is kept in good condition. When weaning the foals, it is not a wise policy to feed entirely on hay chaff. At least two feeds per day of long hay is advisable. This keeps the foal from bolting its food, and also keeps its young teeth in order. Water should be accessible to the foal at all times. Should there be greenfeed in the paddocks sufficiently strong in nutriment, the foal will do equally as well turned out with the loose horses as confined in a loose box, and be more contented.

Some people condemn the practice of handling the foal when running with its mother, their reasons being that it makes the foal mischievous, and when broken to harness is very often a slow and indifferent worker. I have always handled my foals at this age, and so quietened them that I could go up to them anywhere in the yard. I find it a great advantage should they require medical attention or treatment in any way. I have never found them turn out sluggish workers, and some of my most active horses in the past have been developed from foals possessing the quietest dispositions.

Much care should be given to the mares after they have proved to be in foal. In careful hands it is quite safe to work the mare to within a fortnight of foaling. It keeps the mare from becoming too fat, her muscles do not get flabby, and she is in much better condition for foaling than if she had been running idle in the paddock. A careful watch should be kept on the mare about the time she is due to foal; some mares foal easily, whilst others require assistance at this time.

As soon as it has been ascertained that everything is in order and the foal has had a drink, the mare should be left alone and kept as quiet as possible. The mare should not be allowed to mix with the other horses until they have become accustomed to seeing the foal and the foal itself has become strong on its legs as well. Very few horses will kick a young foal, but there are exceptions, and these must be guarded against.

Do not attempt to wean the foals in a barb-wire enclosure. Many young horses have received ugly disfigurements, and in some cases permanent injuries by this abominable practice.

PIGS ON THE FARM.

[By Mr. C. W. JOHNS, Wudinna.]

(Central Eyre's Peninsula (Wudinna), October 5th.)

A very considerable amount of thought has lately been devoted by farmers to the question of adopting sidelines as an additional means of raising revenue. A great deal of space has also been devoted to the subject in the press, some of which articles being over optimistic and unpractical, showing a decided lack of practical experience in farming. Bearing this in mind when setting out to write this paper, I headed it with a question, "Can farmers on Eyre's Peninsula and the West Coast make pigs a profitable sideline?" I must confess that my experience of pig keeping is somewhat limited, but I have had a little experience, and for some considerable time have been keenly interested in the subject and have taken particular notice of that which has been written on the subject by those who claim much experience. It is my hope, therefore, that it will interest members and stimulate inquiry so that we shall eventually be able to develop pigkeeping as a profitable sideline.

The Possibilities of the Export Trade.—At the present time many are holding quite a fair number of pigs of various sorts and wondering how to dispose of them at profit. If we take into consideration the factors of our isolation from the mainland, our lack of population, coupled to the fact that Adelaide and probably the Eastern States are already well supplied, we shall be forced to the conclusion that our only hope is the export trade. I strongly believe that if we can get a reasonable price for our pigs (I use the word reasonable as I am not prepared to say what that price should be) we shall have few other troubles to contend with. We have a healthy climate, plenty of space, and an abundance of cheap feeding material, and I think that it will be profitable to feed them with wheat, at any rate while it is under 3s. a bushel.

We are told that those who contemplate competing in the export market must study the importers' requirements and fulfil them. Great Britain imports large quantities of pig products annually from foreign countries, and only a small percentage from Australia, and I believe that in spite of the geographical position of this country—which is a natural disadvantage—we shall in a few years' time supply a much larger quantity to Britain, because we have the decided advantage of being able to produce cheaply to offset the high costs of transportation. To share this trade we have to send the right type of pig, fattened or grown to a decided standard, and keep up a regular supply at a cost to us commensurate with the price returned.

The Type of Pig Required.—Up to the present, returns from cargoes exported have been disappointing, but in fairness we must allow that our shipments to date have not been of all one type and weight and prime. At the present time we are using a variety of breeds, and it would be necessary to scrap most of these and go in for the sort the British bacon curer requires.

At a recent conference in England between representatives of the National Farmers' Union and bacon curers, the conclusion arrived at was that the Large White crossed to the Mid York was the most suitable. This cross also, I notice, came out on top at some recent trials at Roseworthy College, but it appears to me that the dam might equally well be a Berkshire or Tamworth-Berkshire.

Breeding.—In selecting the boar and sow, the boar should have a deep, broad chest, the shoulders narrow on top and the back long and narrow, and one should note how many defunct teats it possesses; it should not have an odd number. These characteristics are passed on to the offspring. The sow should be similar in build to the boar, but a little more roomy in the back, and should not have less than 12 teats. Both parents should be active, *i.e.*, they should be of the type prone to put on fat instead of muscle. Neither should be used until at least eight months of age, or they will not have completed development, and will produce defective litters. Sows, except gilts, seldom miss 112 days, and when the milk is noticed appearing in the teats they should be under observation, as it usually means another 12 hours to birth. At this stage it is advisable to give the sow—as a precautionary measure—a dose of sulphur, 2 tablespoonsful. To induce her to take this, make it palatable by mixing with dripping and milk. As they seldom take food the day of birth, or the day after, dosing would be difficult then, but sulphur has a delayed action, and further medicine should not be necessary.

When a sow goes over her time some of the litter will often possess long black teeth, these must be extracted, or they will damage the sow's teats, resulting in the youngster getting no milk. Always remove the afterbirth, for if the sow eats it it will often bring on the habit of pig eating. This objectionable habit can often be cured by giving the sow salted pork thrown to her in small lumps and until she will eat no more. Many otherwise valuable pigs have often been slaughtered on account of this trait. It appears to me to be a mineral deficiency disease and somewhat akin to the cow and bone chewing habit, the salt acting as a corrective.

Generally speaking, pigs are fairly free from disease, especially if kept clean and given plenty of charcoal and a mineral mixture in the form of a salt and super lick. Litters intended to be marketed as baconers should be kept on the teat until 8 weeks old, or they will not make quick growth.

Feeding.—The modern method of the open yard or small paddock with greenfeed and small wind and rain shelter is the best housing, and will be ultimately adopted by all. The most economical ration will naturally depend upon the price or cost of the ration. At present wheat is the cheapest when the units food contained in it are considered, but, of course, we must keep it in our minds that a diet of wheat and water will not produce pigs suitable to compete with the Danish product now on the English market. If we can add to our wheat skim milk (or, as a substitute, meat meal) and green feed such as lucerne, our pigs should thrive.

To make a quick return of bacon and a 150lb. pig with a maximum of 2½in. of back fat, which seems to be the desirable size, it will be necessary to study feeding, especially as this also affects flavor of the meat. It should be ready to market at 20 to 25 weeks from birth. To keep down excess fat, a pig must be kept moving. This is where the paddock system of feeding is useful.

Pig Clubs.—It does not seem possible to make pig raising a sideline unless we are prepared to go "the whole hog," both in management and selling. It is often said that our Bureau papers do not carry suggestions for bettering conditions. I therefore offer here as a practical suggestion, that each Agricultural Bureau form a pig club. Such a club is very necessary and would help us considerably in organising the business. Such a club could have as its objective the collection and sifting out of all matters pertaining to pigs; it could inquire into such vital matters as freight and shipping. The cost of producing could be worked out, and probable returns estimated. Its members could co-operatively purchase stock, and by systematic breeding to time table could produce a joint truckload or shipload at any desired time, and probably if a chain of clubs were established, and worked with enthusiasm, we should find it also profitable to ship our lambs under the same organisation.

Mr. A. Kidman (Chairman of the Mount Compass Branch), who was visiting Wudinna, stated that the Bureau Branches should be the pig clubs mentioned by Mr. Johns, as usually only a few members joined clubs. One of the main considerations in keeping pigs was to see that conditions were warm in the winter and cool in the summer, with plenty of water.

Mr. A. J. Shepherd referred to the necessity for a market, and thought that the difficulty would be overcome by the factory at Port Lincoln, which he hoped people would support.

Mr. Barlow (Chief Dairy Instructor) pointed out that the type of pig required to-day was quite different to that of four or five years ago. Farmers should obtain the right type, as the time was long past when any type of pig brought top prices.

If farmers bred the export type of pig any surplus over local requirements could be exported. England required a white pig, as it was more appetising than other types. Consumers did not want fat bacon, and he thought that higher prices would be obtained where there was no more than 1in. to 1½in. of back fat. He advocated rearing pigs in open small paddocks (two to three acres). Many farmers have run pigs in the open on green feed with plenty of water and found it was most economical—particularly where self-feeders were provided. Small paddocks should be spelled occasionally to lessen the chance of disease. He advised his hearers to procure copies of the Department of Agriculture Bulletin on Pig Feeding Experiments at Roseworthy College.

PREPARATION OF THE MERINO WOOL CLIP.

[By MR. W. E. BRYANT, Cummins.]
(*Cummins Conference, October 7th,* 1932.)

In the preparation of the wool clip two things are very necessary—a rolling table for wool rolling and piece picking, and a broom for keeping the shearing board and floor clean. For the wool table I recommend one 10ft. to 11ft. long and 4ft. 6in. wide and 30in. to 33in. high.

For a farm clip of 500 to 800 sheep, including lambs, I suggest two main lines of fleece wool—AA to consist of all the longest stapled, lightest conditioned, and brightest fine wool. A would be similar in quality, but mostly shorter in length and heavier in condition and generally less attractive in appearance. Any very short stapled and heavily conditioned wool should be kept separate; this also applies to very strong or coarse wool and tender or broken stapled wool. If there is enough wool from these lines to make one bale of each sort, I would brand the short stapled, heavily conditioned wool C, the strong wool B, and the tender or broken stapled wool "Fleece."

Starting from the shoulders, the fleeces should be cleanly and evenly skirted. If free from burr, very little need be taken off, except the sweaty edges and stained wool. Should the lower edges of the fleece be burry, and the balance free from burr, the burry wool should be taken off; but I do not advise heavy skirting if the whole fleece is burry. If the back wool has perished and is dirty in appearance, it should be taken out and branded "backs." This should be done on most farms, as the sheep are generally used on the cultivated land, and get very sandy on the rump and back.

When rolling the fleeces, they should be turned over twice from one side and rolled from the breech; this leaves the best part of the fleece—the shoulder wool—exposed. For the average farm clip one line of pieces is sufficient. Should two lines of pieces be made it is advisable to brand them "A pieces" and "pieces"; on no account brand them "firsts" and "seconds." This rule applies to all lines of wool, including

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,
CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.
TELEPHONE: CENTRAL 4855 and 4856.

lamb's wool, as many buyers are instructed not to buy seconds in any line, although a line of seconds from one clip may be quite equal to a line of firsts from another clip. If branded seconds, the buyer often has to pass them. All belly wool should be kept separate and branded ''bellies.''

All stained wool from breech and bellies should be kept separate and dried; urine stained wool will not scour white.

If there is enough lamb's wool to make two lines I would advise making two lines. ''A lambs'' to consist of all the longest stapled, lightest conditioned, and brightest free wool; ''lambs'' would be the short, heavy, and burry lamb's wool.

If one has 450lbs. or more of lamb's wool it is better to try and make two bales of about even weight instead of one very heavy bale and one light bale. This applies practically to the whole of the clip.

The minimum weight of a bale of wool is, Merino 250lbs., crossbred 225lbs., lamb's 200lbs. Anything under the above weight is termed a lightweight bale, and sold separately. Lines of three bales or less are known as star lots, but the wool brokers interlot these lines, if possible. Now that this is done, the old fear about star lots has practically disappeared. All bagged wool is reclassed and sold in lines, although the grower has to pay ½d. per lb. for the reclassing, he usually gets a better price per pound for the bagged wool owing to more competition for it in much larger lines.

Crutching.—As part of the preparation of the clip I strongly advise crutching all sheep during autumn, as the wool from autumn crutching is fairly clean and of some value, but when left until plenty of green feed is about sheep get very daggy and a great deal more wool is stained, which means a reduced price per pound and sometimes a complete loss. If the sheep are not crutched they generally have to be dagged before shearing.

Branding.—As stencil plates are very easily cut out of ordinary flat galvanised iron I advise cutting the following plates:—Owner's initials or name, name of farm, pieces, bellies, locks, lambs, and letters A, B, C, numbers 1 to 9 and 0. The No. 6 will also do for 9. Brand all bales on top and front of bale, owner's initials or name first, name of farm next, class of wool, such as AA or A, and number of bale last. Brand all bales in consecutive numbers, from 1 upwards. On no account have duplicate numbers.

As jute fibre will not take the same dye as wool try and keep all ends of twine and jute fibre out of the wool. For shear cuts during shearing or dressing fly-blown sheep avoid tar or any preparation containing tar. Try and keep all lines of wool as even as possible and avoid false packing. If in doubt as to which line in which wool should be placed, always put it in the lower line. It is better to lose a little on a few fleeces than on the whole line.

Carelessness does not pay in any industry, and the wool industry is no exception to that rule.

GREEN FODDERS.

[By F. J. Jericho, Cummins.]

(*Cummins Conference, October 7th,* 1932.)

From personal experience I have found that green fodder is one of the most important feeds for stock on the farm.

The principal fodder I adopted for winter was Burr Clover, having a small paddock with clover which was kept free from stock until all was dry, putting the sheep into the paddock for a day and then into the paddock in which it was desired to establish the clover, and keep them there for a few days, repeating this practice until enough seed was spread by the sheep's droppings.

Another method is to gather the clover straw with a horserake and then use a strong broom to sweep the burrs together. When sowing the seed by the drill, put the sweepings over the winnower. It is best to sow the seed when sowing oats, either in the super or in the oats. It will germinate better on the ground than when sown too deeply. Clover will make good growth on new land which has carried one crop. I have five acres of new land cropped with wheat, which was too poor to reap at harvest time. The following year I put barley on it with 90lbs. of super, and reaped 12bush. to the acre. As the seed was spread there the previous year the sheep had the feed and straw, and nothing was left to burn but the bushes, and the bushes had to be cut every year.

Last harvest all the clover straw was gathered—approximately more than 1 ton to the acre—and at present the feed is 25 per cent. better than the last. I have not seen any in the district equal to it. The 200-acre paddock, of which the biggest portion is a mat, would average a bigger percentage than that previously mentioned. For summer fodder I have tried Johnson and Sudan grasses. Both are good, but do not germinate too well. Early frosts will cut the Sudan grass.

Wimmera Rye grass is good for late winter feed; stock readily eat the dry straw, which is softer than water grass or any kind of straw. I would class Wimmera Rye as a weed on fallow should early rains fall. Nothing will beat dandelion for an early weed. The best of all fodders is lucerne; it is somewhat difficult to start because the seed must be sown on fine soil and at very shallow depth. It is pleasing to see a green paddock of lucerne in summer when all other feed has dried off. It grows quickest on limestone rubble. A dressing of super every year will improve its growth wonderfully.

DOES IT PAY TO RAISE LAMBS FOR THE FREEZERS?

[By Mr. W. P. Cooper, Koppio.]

(*Cummins Conference, October 7th,* 1932.)

From the little experience I have had I think it pays to raise lambs for the freezers. Of course, one must use the English breed of rams to get anything like good results. I do not think it is of much use trying to raise Merino lambs for this purpose as they do not fatten as well as the cross-bred lambs, nor do the carcasses look anything like as attractive as the cross-breds. They are also much more likely to be affected with grass seeds, which must be avoided. Buyers strongly object to lambs affected in this way. The Merinos are also much more likely to be struck by flies which cause no end of trouble. To raise lambs for freezing use big framed, full grown, Merino ewes joined with English bred rams. By using the Merino ewe one has the advantage of the good fleece of wool, and can also raise a fairly good type of lamb.

There are, of course, many different breeds to select from, and it remains to be seen which breed will suit this particular district. The Southdown ram seems to be well favored in many places. I have selected Dorset Horn rams and joined them with Merino ewes and the results have been very satisfactory, the lambs produced maturing very quickly and presenting a very pleasing appearance; and they also seem to be very easily contented. Out of 66 of these lambs taken to the freezers last season I had 60 first grade, five second grade, and one reject through deformity. With 21 Merinos, which were the pick of over 200, the result was six first grade, eight second grade, six third grade, and one reject. From this it can be readily seen that one must have cross-bred lambs to get good results. Further, the difference in the price of each truckload was:—Cross-bred, 21 lambs, realised £10 12s.; Merino, 21 lambs, realised £7 15s. 11d.

FALLOWING.

[By T. D. VOGT, Yeelanna.]

(*Cummins Conference, October 7th,* 1932.)

To derive the best results from cereals, the crops should be grown on bare fallow. Fallowing means ploughing the land at suitable intervals during the year previous to sowing the crop and allowing it to rest in the interval. Bare fallow enables the farmer to conserve extra moisture for the coming crop, and also the cultivations necessary to do this afford favourable conditions for the work of nitrification. The process of nitrification proceeds rapidly during fallowing, and so nitrogen is made available. Fallowing stores rain which falls during the months before the crop is sown. The rain penetrates the subsoil in the winter, and by capillary attraction ascends to the surface and escapes in warmer months—the firmer the surface soil the greater the rate of evaporation—therefore, fallowing delays this.

The land should be worked from time to time until free from weeds, and the soil consolidated to within 2in. to 2½in. The surface soil should be loose—this checks evaporation. It breaks the continuation of escape of moisture from the soil below. The earlier the soil is mulched the greater the percentage of rain is caught. During the warm months the soil bacteria are most active, and a crusted surface is not satisfactory for their work.

The loss of moisture through a tight compact surface is enormous. The action of water is similar to a lamp wick—the lower moisture rises to the surface and is lost by evaporation. It is not necessary that the surface mulch should consist of finely pulverised soil, in fact it is preferred to be rather rough with small clods, provided looseness is maintained. A crusted surface also does not permit of sufficient aeration and, should heavy rain fall, does not receive its maximum benefit.

Fallowing should be commenced as soon as possible after seeding. Early fallow receives the advantage of the winter rains. Fallowing early conserves the maximum amount of moisture and the rains assist in packing the lower soils, and preparing a solid seed bed. The earlier the fallow the more autumn and winter rains are caught. Once created, the fallows should be maintained; considerations which govern this are weed growth and maintenance of seed bed. Never let the soil dry out in the sod; harrow in late winter or early spring. Where possible, after summer rains, cultivate the fallows. Many fallows are worked well up to a point, and then let go. Retain the fallows in the best possible tilth. It is not wise to work any soil when it is too dry; it is just as bad to work heavy clays too wet. It should be done when the soil is crumbly. Do not do it when convenient to you, do it when it needs it.

The type of instrument to use is important. The best are harrows, scarifier, skim plough, and spring tined cultivator. The number of times the fallows should be worked is governed by the number of useful rains, and the amount of weeds developed. Set your moisture trap before it rains. Fallowing means an extra bag or two to the acre to you. Remember you are making moisture, making the right sort of seed bed, and enabling the bacteria in the soil to manufacture nitrates, thus enriching the soil.

The conservation of moisture increases the supply of available plant food. Bare fallow enables the farmer to have larger areas available for the drill, so that he can concentrate on sowing the crop at the correct time, and whenever favourable conditions occur. Fallowing has also the tendency to destroy the spores of disease, especially takeall. Fertilise, fallow and sow in the belief that the season will be a dry one; you cannot go wrong if you do that. In conclusion I advocate the following slogan:—Sow your wheat on fallow; fallow early.

RABBIT DESTRUCTION.

Paper submitted by Mr. M. A. Palm, Cummins, for the Conference of Lower Eyre's Peninsula Branches at Cummins on October 7th, 1932.

Owing to the alarming extent to which rabbits increase under conditions which are favorable to them, it is well to point out the importance of every landholder doing his utmost to keep the pest in check. There is no doubt that when left unchecked, rabbits cause a great deal of damage to crops and pastures, and cause heavy losses, both to the farmer and to the State each year, from the amount of crops which are eaten off. Many farmers go to endless trouble to reduce costs of production, and yet leave the rabbits go on unchecked. The purpose of this paper is to give an outline of the methods we have adopted with a good measure of success, and if every farmer would spend a few days two or three times each year, the rabbit nuisance could be kept well in hand, in the farming areas at least.

For quite a number of years we have used exhaust gas to fumigate the warrens, and I am quite convinced that this method is 100 per cent. efficient if carried out with care. The method we adopt is to fit a length of flexible hose about 15ft. long to the manifold of an old car engine, keeping all joints tight, and not allowing the gas to escape. The hose is put in a hole on the wind side of the burrows, and the hole is then closed up. The engine is set to run at a fair speed, and the mixture is then enriched as much as possible without causing trouble through fouling the plugs, either by unscrewing the jet, or withdrawing the choke, whenever the smoke appears the hole is closed up, and in the event of there being any holes from which the smoke does not appear, the pipe should be put in these because there are occasions when the holes are not all joined up, though this is very rare. The engine is then left running for five to ten minutes, thus ensuring a thorough circulation throughout the warren. The hose may then be removed and the job is complete. One man can manage the job quite easily where the burrows are small, but where they cover a big area it is much better to have two men on the job in order to fill in the holes as rapidly as the smoke appears. The method is very cheap considering the number of holes which can be treated in one day. It is a great advantage to fumigate the burrows soon after the paddock has been cultivated, because where there are bushes or other cover there will always be a few stray rabbits that are not in the burrows, and these are disturbed with the working. It is only these outside rabbits which will again open up the holes after fumigation. It it is not convenient to attend to the burrows soon after working the paddock, a good active dog will start up many rabbits which are squatting about, and drive them into the burrows. The method outlined is very effective in killing all rabbits in the holes, but unless the burrows are destroyed in some way the few outside rabbits will soon open up all the holes again, and even a few rabbits will very rapidly breed up.

A method found to be very effective is to plough in the burrows with a single-furrow plough; remove the mould-board and let the plough in as deep as it will go, and unless the burrows are close to scrub, it is rarely they will ever be dug out again. Rabbits like a good deal of cover, and they will not often dig new holes in an open paddock. In order to make the job really effective it is a good plan to go around again and fumigate any holes which may have been opened up after about three weeks or so. The eradication of rabbits is much more difficult where there is scrub adjoining, but it will usually be found that there are many burrows in the scrub which can be treated with very beneficial results. A good number of rabbits can be poisoned fairly readily when feed is scarce in the summer months by mixing about half an ounce of strychnine with a tin of raspberry jam, and smearing a small amount on stumps or the like, along pads, &c. Although large numbers of rabbits may be destroyed by trapping, poisoning, shooting, &c., I do not think anything is so effective and so easily carried out as fumigating with the exhaust gas and ploughing in the holes afterwards.

An individual farmer will have a very hard task endeavoring to keep the rabbits in check unless he also persuades his neighbor to do his share, because it is by co-operation that any real success can hope to be achieved.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

DAIRY CONFERENCE AT MOUNT BARKER.

The following resolutions were carried at the Dairy Conference held at Mount Barker in May last:—(1.) "That this Conference of Dairymen meeting at Mount Barker on May 12th, 1932, demand that the Government amend the Dairy Act of 1929:—1. By appointing an Advisory Dairy Council to govern and regulate the whole of the dairying industries in South Australia. 2. That 50 per cent. of the Board consist of members elected by a majority of the cream suppliers with an independent chairman, and that power be given to the Advisory Council to fix all payments for butterfat."

(2.) "That this Conference recommends that the regulation under the Dairy Act, dealing with the grading of cream, enforce the fact that factories be compelled to notify suppliers as to the grade of their cream and stipulate that the respective grades are paid for at preferential rates".

(3.) "That this Conference co-operate to inaugurate a movement to reduce the manufacturing charges of butter".

The above resolutions were referred by the Advisory Board of Agriculture to the Australian Dairy Produce Interstate Committee, and the appended reply, dated July 26th was received from the Committee's Secretary (Mr. C. Harding Browne):—

"Your letter of July 4th, setting out the text of various resolutions adopted at a Conference of Branches of the Agricultural Bureau held at Mount Barker in May, has been considered by my Committee, and I have been desired to reply thereto as follows:— Whilst recognising the close inter-dependence of the manufacturer and the producer in the butter industry my Committee cannot admit the right of the supplier to any form of control in the industrial and commercial matters of manufacture, marketing, and price-fixing. The manufacturer of butter, like the manufacturer in any other industry, buys his raw material and from the moment the property in the material passes to him he has to bear all risks. He immediately becomes liable to the supplier for payment for the butterfat, and thenceforth he has to carry multitudinous risks, such as deterioration, movement of the market, bad debts, &c. It is admitted that a peculiarity exists in this industry in that the seller places himself in the hands of the manufacturer for the correct measurement of the quantity and quality of the raw material delivered. The very circumstances of the trade make this inevitable, and realising this the Government has set up adequate machinery for seeing that this trust imposed by the supplier in the manufacturer is not abused. This machinery includes the filing of monthly returns by all manufacturers, full powers to audit records to ascertain that such returns are true, and the widest possible powers of general inspection, in addition to which all suppliers have the right to call upon the Chief Dairy Instructor to make particular and detailed checks. With this unusual feature adequately covered so as to protect the supplier the position of the butter manufacturer is, we repeat, in no way different from that of any other manufacturer. From this emerges the fact that the term 'manufacturing charges' is a misnomer. A charge cannot exist without there being some second party to the charge, and as the raw material, immediately it has been measured, becomes the property of the manufacturer, the element commonly called 'manufacturing charges' is his calculation of the expenses of manufacture and marketing, and provision for his profit. These expenses cannot possibly be constant, because the butter is sold not only in Australia, but to numerous buyers in Great Britain and the East, and it rarely happens that all butters command exactly the same price. The manufacturer aims to allow a margin that on the average will be adequate. No instance is known to members of my Committee of parties who carry no financial responsibility for the operations involved being given even partial control of an industry. It is true that Parliament regulates the charges of such monopolies as the gas and electric light industries in this State, but this power is exercised because of the privilege of monopoly which Parliament grants the companies rendering these services. When the producer asks for control of the commercial functions in the dairy industry he is not in a position to confer upon the manufacturer any compensating protection. The manufacturer is left open to the full blast of free competition and the risks of the general economic situation. It is he who in the long run has to meet his wages bill and his obligations to his creditors, and consequently he holds that demands for control of his ordinary commercial operations can find no support in either equity or precedent. Furthermore, the existence of a Government Butter Factory and the active presence of its representative upon the Price-fixing Committee is sufficient guarantee that manufacturers are not extracting unjustifiable profits from the industry. If this were so it would be reflected in the trading results of the Government-owned factory, but reference to the report of the Parliamentary Standing Committee on Public Works on the Port Adelaide Freezing Works and Butter Factory, and to subsequent reports of the Auditor-General, will show that its profits from the manufacture of butter, even when they occur, are negligible. This is an important fact, because the Government Butter Factory was intentionally established as a 'check' factory. Also on the Price-fixing Committee are the representatives of two large co-operative organisations established and controlled by primary producers. In fact, we can think of no other industry in the State where the sellers of a raw material have such facilities for exercising influence upon the buyers of the product as they have in the butter trade. The foregoing remarks cover the questions raised by the resolutions 1 and 3.

"All that need be said in respect of resolution 2 is that for several months factories have been so notifying suppliers, and have even gone to the extent of enlisting the assistance of the Government Dairy Inspector to see that the policy is carried out in a thorough manner.

"Finally, we refer to your request for a statement showing how the price of butterfat in Adelaide is reconciled with the London price of butter, and here we are confronted with the principle dealt with above. We have not heard of wheatgrowers claiming a right to demand an explanation from merchants as to how the local price of wheat is reconciled with the price in Liverpool or Chicago, or similar demands from the breeders of cattle and the growers of apples. All merchants are compelled to take into consideration a multitude of factors, all of which may, and frequently do, vary from day to day, so that it requires a close knowledge of the particular brand of commerce concerned even to be able to follow the calculations involved. An explanation that holds good to-day may not apply correctly at another date, and in setting out the position at any given time there is a danger that when departures from it are observed they will be regarded suspiciously by outsiders not familiar with the factors operating. Consequently you will see that your last request confronts the members of my Committe with two difficulties—(1) They do not grant that they, more than any other merchant or manufacturer, are required to make public their commercial calculations; and (2) they are alive to the danger of any such information, if given, being gravely misinterpreted by those unfamiliar with the countless factors bearing upon their affairs. But although firmly maintaining this position, they desire to work amicably with all other sections of the industry, and in the hope that a concession to your request on this occasion will help towards this end they have authorised me to give merely as an instance the method followed in establishing the price on Monday afternoon, the 18th July, this information being set out in the attached statements."

1. PRICES—GENERAL STATEMENT.

My Committee incline to the view that many of the confused ideas regarding the price of butter arise from the fact that the prices shown in the cabled market reports from London are accepted by readers as if these were the actual prices realizable instantaneously by manufacturers for stocks in Adelaide. It should always be remembered that the cables give only the price of butter actually "on spot" in London, whereas butters leaving the South Australian factories at that date cannot arrive in London until six weeks later. Owing to this delay it is fallacious to attempt to find absolute agreement at any given date between London and Adelaide prices. If a long period is taken for comparison, a complete year for instance, a close agreement will be found to exist.

South Australian butter manufacturers, as well as those in other States, have found that because of this constant fluctuation in the London price, the figure offered by London merchants for butter F.O.B. Adelaide or C.I.F. & E. constitutes in the long run the most reliable basis from which to work prices.

The attached statement "A" is a calculation of the price realised by the manufacturer on the basis of sales at 103s. (sterling) per cwt. in London for butter sent to that market on consignment.

Statement "B" is a similar calculation on the basis of C.I.F. & E. London sales at 101s. (sterling).

These prices have been adopted for illustration because, as indicated in the final paragraph of our letter, they formed the basis adopted by the Committee in establishing the local price on the 18th instant. Normally the price is fixed every Monday afternoon on the quotation then ruling. The fluctuating nature of the London market already referred to makes variations during the week inevitable, but, as will be readily realised, the average is found to be fair. It is an impossible ideal to make the local market move in detailed sympathy with the London market. To illustrate this aspect of the question, although 101s. C.I.F. & E. was taken as a basis for the week commencing the 18th instant, in the latter part of the week 99s. was the maximum price obtainable. In this manufacturers suffered, but, of course, compensation comes when the movement is in the other direction. It is, to repeat, the average position that must always be used as a basis for comparison.

2. Statement A.

Net return of manufacturers of butter shipped on consignment and sold in London for 103s. per cwt., which was the spot price in London last week.

		Shillings Per Cwt.
Choicest butter sold in London		103.00
Less London charges, including port dues, lighterage, landing, housing, delivering, rent, cabling, trade discount, commission, and Del-credere risk—which average 4¾ per cent.		4.89
		98.11
Plus 25 per cent. exchange		24.52
		122.63
Deduct freight to London, 8s. per cwt., plus 18 per cent.	9.44	
Insurance at 6s. 10d. per cent., plus 25 per cent.	.41	
		9.85
		112.78
Add Paterson bounty		28.00
		140.78
Less Australian charges (cost of cases, freezing, wharfage, cartage to Outer Harbor and putting aboard, Commonwealth grading fee, and Dairy Council levy)		6.83
		133.95
Less levy to Paterson plan		16.33
		117.62

Net price to manufacturer in Adelaide on butter sent on consignment and sold in London at 103s. per cwt. would be 117s. 7d. per cwt. in Australian currency.

3. STATEMENT B.

Net value to manufacturer—in Australian currency—of butter sold at 101s. per cwt. C.I.F. & E., London.

		Shillings Per Cwt.
Value of choicest butter		101.00
Deduct London selling agent's commission of 1 per cent.		1.01
		99.99
Add exchange at 24.75 per cent., this being the rate obtained on demand draft		24.75
		124.74
Deduct freight to London at 8s. per cwt., plus 18 per cent.	9.44	
Insurance at 6s. 10d. per cent., plus 25 per cent.	.41	
		9.85
		114.89
Deduct Australian charges (cost of cases, freezing, wharfage, cartage to Outer Harbor and putting aboard, Commonwealth inspection fee, and Dairy Council levy)		6.83
		108.06
Add Paterson scheme bounty		28.00
		136.06
Less levy to Paterson plan—1¾d. per lb.		16.33
		119.73

Which is equivalent to 1.83s., or 12.83d. per lb. net to the manufacturer. As the price being paid by most manufacturers for butterfat is 1s. per lb., it will be seen that from the "over-run" the manufacturer received 2.66d. per lb. to cover the cost of manufacture, interest, depreciation, and profit.

The foregoing shows the result, as already stated, where the manufacturer actually secured 101s. for his butter—not all manufacturers succeeded in doing this.

AGRICULTURAL BUREAU CONFERENCES.

Conferences of the Branches of the Agricultural Bureau situated on Eyre's Peninsula were held at Kimba, Wudinna, and Cummins on October 3rd, 5th, and 7th respectively. Departmental officers present were:—Professor Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director), H. B. Barlow (Chief Dairy Instructor), C. T. McKenna, B.V.Sc. (Veterinary Officer Stock and Brands Department), H. D. Adams and W. H. Brownrigg (Agricultural Instructors), and H. C. Pritchard (General Secretary Agricultural Bureau).

THE KIMBA CONFERENCE (EASTERN EYRE'S PENINSULA).

The Kimba Conference was poorly attended, only four Branches sending representatives, viz., Kelly, Pinkawillinie, Balumbah, and Balumbah Women's.

Mr. T. H. Harris presided, and the Conference was opened by Professor Perkins who congratulated the State, and the Kimba district in particular, on the prospects of a good season. Last year Eyre's Peninsula produced 10,000,000bush. of wheat and he was confident that the ensuing harvest would be greater. In many instances good seasons were freak years, and there was need for caution in basing farming practices on the experiences of those years. He regarded South Australia as a country of relatively low rainfall with a short growing period, and all farming practices were built up on that point of view. The most successful farmer was one who was able to judge the results of average seasons and who carried out his practices accordingly. Last year the State had a mean yield of 11¾bush. per acre, and in 56 years there were only six years with a higher average, and it would be wrong to base farming practices on a season such as was experienced last year. It was known, for example, that early, well worked fallow gave higher yields than late tillage, but in good years the latter might be of greater advantage. In an average year good results were not obtained without superphosphate. If certain varieties succeeded well only in a good season it was folly not to sow varieties which were known to give the best results in average years. For these reasons alone he considered that farmers should be aware of being tempted to change their practices on the experience of a good season. It was satisfactory to note that side lines had been taken up in this part of the State. Whilst the market conditions were not satisfactory for eggs and fat lambs, it was gratifying to know that farmers on Eyre's Peninsula were, at any rate, obtaining prices for their cream at Port Lincoln equal to Port Adelaide prices.

Papers were read by Mr. G. W. Cant (Kelly) on "Starting on a Virgin Scrub Block"; Mr. A. Jericho (Balumbah), "Dairying in this District"; Mr. F. A. Gallaway (Kelly), "Farming Records"; and Mr. F. Masters, "Development of Mallee Farms."

Questions were answered by Departmental officers, and the following resolutions were carried:—

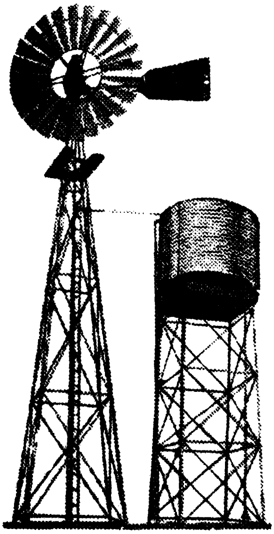
That the next Conference be held in July at Cowell under the auspices of the Miltalie Branch.

That this Conference urges the Farmers' Relief Board to grant super sufficient to dress land as recommended by Departmental officers.

That the price of superphosphate be reduced.

Metter's Master "Nuoil" Windmills

AGAIN AWARDED FIRST PRIZE, ADELAIDE SHOW, 1932.



Most Reliable, Efficient, and Durable.
Positively Self Governed.
Greater Lifting Strength.
Will Pump More Water on a Lighter Breeze.
Equipped with interchangeable and replaceable bearings of high-class anti-friction metal.

MANUFACTURED IN SOUTH AUSTRALIA BY

Metters Limited,
NORTH TERRACE, ADELAIDE.

"No fear of a Drought
With a Metters about."

That this Conference recommends that a further grant on the same lines as the £20,000 just allotted be made available for farm employment in order to increase primary production, exports, and revenues of the State.

That the Kimba District Council be asked to enforce the Noxious Weeds Act.

That this Conference recommends that the Department of Agriculture establish experimental plots in the Kimba district for testing the values of pastures suitable for the locality.

That this Conference protests against the unfair treatment of telephone subscribers who are cut off from a house where a service has been established, but has been disconnected owing to the inability of the proprietor to pay his rent and calls.

That this Conference endeavors to influence the Government to destroy rabbits on water conservation reserves.

That the Government be asked to provide settlers adjoining unoccupied land with wire netting through district councils or the vermin board on the old terms.

Mr. C. T. McKenna delivered an instructive address on the "Care of Farm Animals" and replied to numerous questions relating to stock complaints.

THE WUDINNA CONFERENCE (CENTRAL EYRE'S PENINSULA).

There was a fair attendance at Wudinna when Mr. A. W. H. Barnes presided over the Conference of representatives of Branches from Wudinna, Minnipa, Pygery, Pinbong, and Kyancutta.

The Conference was opened by Professor Perkins, who stated that prices for wheat were slowly approaching the cost of production, which varied from district to district, from season to season, and from farm to farm. A good deal depended on individual management, but the yield was, of course, a more important factor in production cost. For 70 years the average in South Australia was a little over 8bush. In recent years the average was slightly better owing to the extension of good farming methods. More farmers have approached the standard of the most successful farmers of the State and in consequence the yields were slightly increased.

Papers were read by:—Mr. C. W. Johns (Wudinna) on "Pigs on the Farm," Mr. A. J. Shepherd (Wudinna) on "Practical Breeding of Draught Horses," and Mr. J. F. Heylen (Pygery) on "Why Fallow and Rotation Cropping."

Discussions arose on the bulk handling of wheat, the advantages of establishing a butter factory in the district, and the best means of using the services of Agricultural Instructors. The following resolutions were carried:—

"That this Conference urges the Government to hasten the Committee's report on bulk handling of wheat, meanwhile giving the Farmers' Union every facility to ship bulk cargoes for the coming season."

"That efforts be made to have the butter factory at Port Lincoln reopened."

"That the Government provide facilities *re* cool storage in trains for the handling of cream and other produce to Port Lincoln."

"That the Government be asked to make provision for receiving eggs at the Port Lincoln Produce Depot."

"That a yearly programme of meetings and visits for Mr. Brownrigg be drawn up and that the formulating of the scheme be left in the hands of Mr. Brownrigg."

"That the title of Agricultural Instructor be altered to Agricultural Adviser."

"That the Advisory Board of Agriculture make inquiries as to the reason why so many bags were undersized and not capable of holding 3bush. of wheat last season."

In the evening Mr. Spafford gave an address on "Recent Research Work in Connection with the Cultivation of Wheat."

Minnipa, Kyancutta and Poochera were mentioned as the place to hold the next Conference, and Minnipa was eventually decided upon.

The Cummins Conference (Lower Eyre's Peninsula).

The morning session at the Cummins Conference was poorly attended, but the number of delegates increased during the afternoon and evening. Mr. G. W. Proctor presided and the Branches represented were Cummins, Yeelanna, Koppio, Kapinnie, and Green Patch. In his opening address Professor Perkins stated that in the Southern Districts of Eyre's Peninsula there were many men who had distinguished themselves in agricultural work. Within recent years the Denton trophy at the Royal Show in Adelaide had been won by Mr. W. E. Cooper in 1929, by Messrs. Lawrie Bros. in 1930 (who were also runners up in 1931 and in 1932), and by Mr. R. Kain in 1932. At this year's Royal Show Mr. R. R. Wilson exhibited the best bag of malting barley. In the competition for the Champion Shield donated by the Royal Agricultural and Horticultural Society for the best wheat crop in the State, Messrs. Smith Bros., Yeelanna, were placed third in order of merit in 1927, Messrs. Aikenhead and Treloar third in 1929 and second in 1931. Farmers in the district were contributing in no small measure to the welfare of the State, and given adequate marketing facilities the district was suitable for the development of farm sidelines.

Mr. M. A. Palm (Cummins) read a paper on "Rabbit Destruction," Mr. T. D. Vogt (Yeelanna) on "Fallowing," Mr. W. E. Bryant (Cummins) on "Preparation of the Wool Clip," Mr. F. J. Jericho (Cummins) on "Green Fodders," and Mr. W. P. Cooper (Koppio), "Does it Pay to Raise Lambs for the Freezers?".

Instructive discussions arose on questions asked by Branches on subjects relating to the advantages in feeding off early sown rank crops, the benefits gained from early fallow and other matters of interest to farmers in the district.

The following resolutions were carried:—(1) "That this Conference requests the Advisory Board of Agriculture to ask superphosphate manufacturers to make a reduction of 5 per cent. for cash with order on established trading custom." (2) "That the Government improve the marketing facilities of poultry farmers on Eyre's Peninsula to enable them to produce at a profit and extend the industry." (3) "That special Government grants be allotted for making roads in the Cummins-Yeelanna district owing to the shocking state of same and the great disabilities primary producers have to work under through this cause." (4) "That oil used for farming operations be included in the list of exemptions of sales tax, which would mean a great relief to primary producers, especially those engaged in power farming." (5) "That the Associated Banks be asked to remove the double increase of exchange on Eyre's Peninsula cheques;" and (6) "That the next Conference be held at Cummins."

In the evening Mr. H. B. Barlow (Chief Dairy Instructor) addressed the Conference on "Dairying and Pig Raising."

The average production of dairy cows in Great Britain is 574 gallons of milk a year; in Denmark, 571 gallons; Germany, 520; Norway, 445; Australia, 290 gallons.

THIS SHOWS THE URGENT NECESSITY FOR IMPROVING METHODS OF FEEDING IN AUSTRALIA WITHOUT DELAY.

ADVISORY BOARD OF AGRICULTURE.

The Monthly Meeting of the Advisory Board of Agriculture was held on Wednesday, October 19th, there being present Messrs. H. N. Wicks (Chairman), A. M. Dawkins, S. Shepherd, A. L. McEwin, J. W. Sandford, P. J. Baily, Professor Perkins (Director of Agriculture), and H. C. Pritchard (Secretary). Apologies were received from Messrs. A. J. Cooke, F. Coleman, and J. B. Murdoch.

Congress Addresses.—It was unanimously decided to extend the sincere thanks of the Board to private contributors to the Congress Agenda for the valuable support they rendered in the Congress proceedings.

Congress Agenda.—It was decided to give effect to the resolutions of Congress that the Agenda be sent out to Branches six weeks before the Annual Congress.

Tariff on Superphosphate.—The Board supported the Congress resolution that superphosphates should be admitted free of duty, and the Secretary was instructed to forward the resolution to the Minister accordingly.

Imported Journals.—Congress resolution: "That the restriction on the importation from America of farm journals be removed." The Secretary reported that the main cause of the high price of literature imported from America was the exchange rate, which he was informed was about 65 per cent. As this was beyond the control of the Board no further action was deemed necessary.

Price of Superphosphate.—Congress Resolution: "As superphosphate was so very essential for the production of wheat and fodders, we consider that a reduction in the price is long overdue. Manufacturers have demanded spot cash for the last two seasons which should enable them to sell at a lower price." It was decided to bring this under the notice of manufacturers.

Barley in Wheat Crops.—Attention was drawn to the alarming extent to which barley was present in wheat crops this season. The Director of Agriculture intimated that he would draw the attention of Agricultural Instructors to this matter and that he would call for reports on the subject.

New Branches.—Conditional approval was given to the formation of a branch at Chilpuddie Rock and a Women's Branch at Mundalla.

Transfer of Branch.—The Board approved of the transfer of the Yorketown Branch to Coobowie.

Life Members.—The following gentlemen were approved as Life Members of the Agricultural Bureau:—Messrs. H. Bowyer (Owen), H. Schultz (Lenswood), R. Wheaton (MacGillivray), H. G. Mackley (Mangalo), E. B. Pitman (Murraytown), and J. B. Makin and W. H. Morcomb (Keith).

New Members.—The following were approved as members of the undermentioned Branches:—Kuitpo—S. R. Gray, G. Allington, W. F. Wilson, G. P. Barker, E. Steer, R. L. Vining, R. Morris, V. Ladhams, T. Dixon, H. Stone; Mangalo Women's—Miss A. James; Upper Wakefield—Paul Glynn; Boors Plains—V. A. H. Prider; Port Elliot—M. A. Littleby; Longwood—Les. Lewis; Kybybolite—B. Paltride, S. H. Castine, H. L. Miles, S. Heffernan, T. Boord; Pinnaroo Women's—Mrs. H. Gilbert, Mrs. G. Pierce; Tatiara—Glen D. Ferguson; Kangarilla—H. C. Dowling; Alawoona—S. Coad; Hindmarsh Island—K. Barclay; Paruna—John Stewart, A. Hinton; Macclesfield—A. Read, K. Read; Greenock—E. W. Nitschke, A. Auricht, J. Jungfer; Clare Women's—Mrs. M. Somerville; Barmera—O. J. Mayger, W. Mutton, J. Pasturel, L. J. Gordon, Ki Ki—A. F. Kiddle; Wilmington—R. C. Cooley, M. L. George; Yaninee—J. L. Roe, F. E. Christian; Mount Hope—E. Russell, L. A. Myers, A. D. Myers; Hoyleton—Roy Sandow; Belalie Women's—Mrs. B. McCarthy; Auburn Women's—Mrs. J. Tansell, Mrs. E. J. Sandow; Aldinga—S. Blacker, Jack Blacker; Gawler River—E. W. Linke, R. White; Taplan—W. Axon; Balaklava—R. H. Shepperd; Weavers—G. T. Anderson, W. G. Agnew; Redhill—Lance Harris; Morchard—F. Stainer; Black Rock—C. Judell,

R. Thomas, Geo. Crowhurst; Owen—G. Poole, S. Lacey; Jervois—L. Railz, J. E. Richards; Hartley—A. B. Brook; Mount Barker—W H. Boyce, T. G. Paternoster; Cummins—Roy Feirclough, Leigh Rough, Hans Kahl; Bowhill—T. W. Morton, G. Morton; Mundalla—E. J. Pavier, A. H. Lucas; Williamstown Women's—Mrs. Wm. Patterson, Mrs. M. Adams; Lenswood and Forest Range—C. Filsell, O. Probert, — Robinson, W. Fry; Taplan—R. Venning, R. Turner; Lameroo—J. Opie, G. Priest; McLaren Flat Women's—Mrs. R. Elliott, Mrs. E. Broughton; Millicent Women's—Mrs. P. Sullivan; Penola Women's—Mrs. J. N. McBain, Mrs. W. Patterson, Mrs. J. Skinner, Mrs. E. R. Ey; Blackwood—C. J. M. Wakefield, J. H. Wakefield; Mount Gambier—G. R. Hellyer, L. R. Headlam; Cummins—John Pedler, P. L. Vanstone, A. Hill, C. Hill, Jas. Rundle; Pinbong—Eric Scholz; Stockport—R. Koch, L. Koch, E. Koch; Modbury—J. R. McPherson; Moorlands—Jack Jaensch; Williamstown—F. Adams, D. Gordon; Balaklava—N. Harley; Yantanabie—Bruce Miller, N. B. Miller, C. G. Miller; Mangalo—R. Hughes, L. Hannemann, M. Evely; Wynarka—G. Martin, C. S. Hall, A. Dalziel, J. H. Priest; Wirrilla—W. B. Hendry; Jamestown—B. McCarthy, H. C. Cavenett; Stanley Flat—L. L. Dux, W. Slattery, J. Slattery, E. F. Ward, S. C. Lee, A. McAskill, R. McDonald, S. McDonald, C. H. Walden, E. W. Burch, E. Burch; Hope Forest—G. Hurst, A. Lewis, F. Bowen, J. Barclay, E. Edmonds, K. Searle, C. Fisher, H. Nielsen, G. Bevan, J. McGee, S. Coad, T. Finchen, F. Eves, W. Catlin, E. Muldoon; Balumbah Women's—Miss Mona Roe, Miss Alice Norris, Miss O. Deer, Miss Alice Deer.

New members, 155; present members, 8,019; No. of Branches, 320.

Meetings.—It was decided that, in future, meetings will be held at 2 p.m. instead of 2.30.

A large number of resolutions from Congress and Conferences was considered in Committee, and Branches will be advised from time to time as to the consideration and recommendations made in connection with such resolutions.

METROPOLITAN ABATTOIRS, ADELAIDE

MANUFACTURERS OF

Meat Meal for Pigs

Read Report of Trials made by PROF. PERKINS,
Journal of Agriculture, January and July, 1921.

Meat Meal for Poultry

The GENERAL MANAGER, Metropolitan Abattoirs Board,
Box 573E, G.P.O., Adelaide.

ALSO MANUFACTURED—

Blood Manure Bone Manure

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. Sandford & Co., Limited, reported on November 1st, 1932:—

Butter.—The production of butter in South Australia during October was greater than in any other season in the history of the State, and the weather conditions being congenial, it is anticipated that supplies will be well maintained well through November. There is an abundance of feed in all areas, so that the dairy herds are in splendid condition throughout, and with the keener attention which is being given to dairying, it is of great benefit to the man on the land and the State as a whole. Heavy quantities continue to be shipped to Britain, but it is unfortunate that prices ruling there are lower than they have been for many years, so that the returns to the farmer are less than it was hoped would be the case. At this time of the year local values are entirely governed by export, and values have eased throughout the month and at date were—Choicest creamery fresh butter, in bulk, 1s. 0¾d.; prints and delivery, extra (these prices are subject to the stabilsation levies); store and collectors, 7d. to 7½d. per lb. at store door, less usual selling charges.

Eggs.—Whilst the cool weather conditions have been favorable for dairying, it has had the effect of shortening egg production, for with changeable temperatures, such as we have had this season, the laying hens are affected. The result has been that the percentage of eggs which is suitable for shipment was greater than usual, and has temporarily shortened the supplies available for pulping and Australian trade generally. It is expected, however, that as soon as the warm weather sets in that there will be an immediate response in production. Meanwhile the market is steady. Ordinary country eggs, hen or duck, 5d. per dozen; selected, tested, and infertile higher.

Cheese.—The tonnage of cheese being manufactured at present is also creating new records, and as the South-Eastern parts are usually several weeks later in seasonal conditions, it is expected tht the cheese manufactured will continue at a high level for a good many weeks yet. This commodity also is being shipped as freight can be arranged, but under the influence of weakening butter prices values have eased. New makes, large to loaf, 7d. to 7½d.; semi-matured and matured, 9d. to 11d. per lb.

Bacon.—The consumption of bacon has kept up very well throughout the month under review, but the curers kept the market well supplied from week to week. Rates also continued steady. With the nearer approach of Christmas, manufacturers are now preparing hams for the trade, and a keener demand was experienced for these, many storekeepers booking their requirements for delivery at little later on. Best local sides, 8½d. to 9d.; best local factory-cured middles, 8½d. to 9d.; large, 8d.; local rolls, 8½d. to 9d.; local hams (raw), 11½d. to 1s.; cooked, 1s. 2d. to 1s. 3d.; lard, prints, 6d. per lb.

Almonds.—A splendid demand for almonds continued throughout the month, but the suppiles to hand were somewhat limited. With buyers unable to obtain all their requirements, it might have been expected that values would have firmed, but owing to the importations of kernels into Australia which will be landed during the next few weeks, this has steadied the values here. Brandis and softshells, 9½d. to 10½d.; hardshells, 6d. to 6½d.; kernels, 2s. 1d. to 2s. 2d. per lb.

Honey.—Except for the local trade there has not been any very heavy sales made interstate. Reports from other parts of the Commonwealth indicate that the stocks of honey are sufficient for their needs, so that there has not been the same call for South Australian honey as in some other years, and it looks as though overseas trade will have to be developed to clear stocks during the coming years. Prime clear extracted, in liquid condition, 3d. to 3½d.; second grade, 2d. to 2½d. per lb.

Beeswax.—Again met with good demand throughout the month, and fairly heavy consignments were received—1s. 0½d. to 1s. 11d. per lb., according to sample.

Live Poultry.—The supplies of live poultry throughout October were somewhat shorter than just previously, but this is usual, as with farmers preparing for harvesting they have not the time necessary for cooping and marketing birds. Towards the latter end of the month supplies improved, but the increase was largely in old and light weight hens, and values were a shade easier for these. Prime roosters, 4s. to 5s. 4d.; nice conditioned cockerels, 3s. 3d. to 3s. 9d.; fair conditioned cockerels, 2s. 8d. to 3s. 1d.; chickens lower; heavy weight hens, 2s. 9d. to 3s. 9d.; medium hens, 1s. 11d. to 2s. 6d.; light hens, 1s. 4d. to 1s. 8d.; couple of pens of weedy sorts lower; geese, 4s. to 4s. 9d.; prime young Muscovy drakes, 4s. to 5s.; Muscovy ducks, 2s. to 3s. 3d.; ordinary ducks, 1s. 8d. to 2s. 6d.; ducklings lower; turkeys, good to prime condition, 8d. to 9½d. per lb. live weight; turkeys, fair condition, 6½d. to 7½d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 3½d. to 5d. each.

Potatoes.—4s. 9d. per cwt.

Onions.—New season's, 13s. per cwt.

RAINFALL TABLE

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of, and to the end of October, 1932, also the average precipitation to the end of October, and the average annual rainfall.

Station.	For Oct., 1932.	To end Oct., 1932.	Av'ge to end Oct.	Av'ge Annual Rainfall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

REPORTS OF BUREAU MEETINGS.

WOMEN'S BRANCHES.

MILLICENT (Average annual rainfall, 29.81in.).

July 15th.—Present: Nine members.

Recipes.—*Home Made Soap*—A tested recipe: Put 1lb. resin and ¼lb. borax in a copper with 11 pints of hot water. Boil until the resin is soft and stringy. Melt 6lbs. of fat (it must be free from salt) and pour into the copper, stir all together; dissolve 1lb. of caustic soda with 3 pints of warm water, use a large tin or enamel vessel for this purpose; while it is bubbling pour into the mixture in the copper, stirring all together. Add ½ a cup of liquid ammonia and half a packet of lux flakes. Boil for 5 minutes then pour into moulds or leave in the copper to set. Draw the fire if the soap is left in the copper. The soap is of a white color when first made. It should be cut into bars or pieces and left stand to dry for a month before using. It will then be of a pale yellow color (Mrs. W. Varcoe). *Melon Pickles*: 8lbs. of melon cut into squares, 4lbs. onions (cut up), 3lbs. sugar, ½ cup salt, 2 quarts of vinegar. Put 1 teaspoonful of cayenne pepper, 2 teaspoons pepper corns, and 2 teaspoons cloves into a muslin bag. Then put all on to boil. When they have boiled, mix together 2 tablespoons of mustard, 2 tablespoons of curry powder, and a little more than ½ cup of plain flour, with enough vinegar to make a smooth paste. Stir into the pickles and boil until melon and onions are quite tender. Stir occasionally while cooking. Bottle while hot and tie down when cold (Mrs. W. Varcoe). *Melon and Apricot Jam*: Cut 3lbs. melon into small squares and sprinkle with 2lbs. sugar, leave overnight, soak 1lb. dried apricots and leave till morning; add another 2lbs. sugar and boil all together for 3 or 4 hours, or until nice and thick. It will jelly on a saucer when done (Mrs. A. Bitschke). *Golden Gate Marmalade*: Take 12 oranges, 2 pints of cold water to each pound of fruit, ½lb. of sugar to each 1lb. of cooked fruit. Wash oranges, cut in halves, and squeeze out juice and pulp. Cut peel into shreds, weigh pulp, juice, and peel, place in preserving pan. Cover with the cold water and stand overnight. In the morning boil until the skin is tender, then weigh cooked mixture, add sugar, and boil for 40 minutes. Cool and pour into hot sterilised glasses and seal; keep in a cool, dark place (Mrs. H. W. Altschwager). (Secretary, Mrs. W. Varcoe.)

PARRAKIE (Average annual rainfall, 14.52in.).

May 26th.—Present: 12 members.

The Dairying Industry.—Mr. E. Fromen, of the S.A. Farmers' Union, in the course of an address first gave a short resume of conditions in other parts of the world and on marketing problems. The United States and Canada were in difficulties. Butterfat in both Canada and the United States during the past winter was down as low as 6d. to 6½d lb. and at present was 7d. to 7½d. lb. fat with a falling tendency. Pigs were 2½d. to 3d. lb., and eggs 6d. to 8d. dozen in the big cities. South Africa, which, like America, was on the gold standard, was just as badly off, and to save farmers from absolute ruination, the Government had arranged to pay a bonus of 6d. lb. on all export butter, and 6d. dozen on all export eggs. Without this bonus their prices would be down to 4d. to 5d. lb. for butter. In Denmark and the Baltic States, the value of butterfat was only about 7d. lb. Germany who at one time consumed 33 per cent. of the World's exportable surplus of butter, had by proclamation stopped imports and was only allowing small quotas to come in, and even when they were prepared to buy, they were putting difficulties in the way of buying, and wanted credit, consequently England was the only market for all the surplus butter from the Baltic States and from Holland, and the only place where the sellers could get cash; it was all pouring into Great Britain in spite of the 10 per cent. duty, and prices to-day were lower than what they were before the duty was imposed. So far as bacon was concerned, Denmark was shipping between 6,000 and 7,000 tons a week of bacon to

England; the other Baltic countries from 2,000 to 3,000 tons every week, and the prices in England ranged from 4d. lb. for Polish bacon to 5½d. and 6d. lb. for the finest Danish. Eggs were not quite so low, and prices had kept up better than butter or bacon. Under these circumstances, he could not hold out any bright prospects of big prices. Farmers must try to produce all the food for cows, pigs, and poultry on the farm and not buy anything outside of the farm, and if this were done, the whole of the returns from produce sold belonged to the producer. Anyone who kept cows and produced milk had the skim milk, which was a very valuable food for pigs or poultry. Skim milk, either fresh or sour given to the poultry helped to make a balanced ration and increased egg production. It should be used with care, and one should not give them fresh skim milk one day and sour skim milk another, that upset the birds. So far as pigs were concerned, there had not been any big expansion, and if the wheat farmers who kept cows studied pig production they would find that they would receive a bigger price for their wheat and barley in the growing of pigs than they received selling same at the railway. Approximately it could be taken as a calculation that every 1d. lb. for pigs represented 1s. bushel for wheat or barley; *i.e.*, at the present time bacon pigs were worth 5d. lb. at the factory. Allowing for the cost of railage, etc., ½d. lb., the wheat would realise equivalent to 4s. 6d. bushel on the farm, if fed properly and carefully to well-bred pigs. The export of pigs had not been very large; a few hundred thousand had been shipped home frozen in the form of porkers, but producers in Australia had not made use of the skim milk, and under proper conditions each farmer keeping cows should breed and sell at least three to four pigs a year for each cow that he kept. A very fine market had been built up in shipping eggs in the shell to England and last year 11,000,000 dozens were sent from Australia, of which South Australia contributed 1,900,000 dozens. The eggs shipped realised to the farmer from 10d. to 11d. dozen, which, taking into consideration the low price of wheat, was a very splendid return, but unfortunately the country egg producers did not share in these prices, and they only received from 4d. to 5d. dozen during the export season, while the professional poultry farmers and the farmers living in the hills surrounding Adelaide had the benefit of the higher prices. The reason for the low prices of country eggs was because they became too stale and had too big an air space before they reached the city, and were only fit to use for pulping purposes. Egg pulp for export could only be produced from cheap eggs, because they had to compete with the Chinese and other egg pulp that was being shipped in big quantities to England. By pulping eggs at those values they had been able to ship pulp from South Australia to England, and altogether some 600,000 dozen eggs had been shipped in the form of pulp. How to deliver the eggs in good condition and have a share in the high prices was what producers wanted to know. This could only be done if it were possible to collect eggs twice weekly from farm to farm, and if in the district within a distance of, say, 40 miles there were 16,000 laying hens arrangements could be made for collecting by motor lorry from the farm twice weekly. In a district with, say, 32 farmers who were running 500 hens each or 64 farmers with 250 fowls each a motor collection could be started. This would be a little expensive, but you would be repaid fourfold for the extra expense. The eggs would be delivered in Adelaide in a condition that most of them would be suitable for export. The motor lorry would also collect cream, and probably arrangements could be made to carry parcels and bring out anything wanted from the township. It must be understood that it would not pay to run a mile or a mile and a half off the road to a farm where only 50 or 100 fowls were running. He placed the number of fowls at the minimum of 250, and there must be at least 16,000 fowls producing on an average of 8 to 10 dozen eggs a year from each fowl to enable the cost of collecting eggs by motor lorry to be met on a reasonable basis. In addition to collecting the eggs, farmers would then have to use more care in looking after the eggs on the farm. The fowls must be provided with water, and if possible, green feed. Nests must be provided where the fowls could lay their eggs under clean conditions. Washed eggs were useless for export, and only clean eggs not washed would do for that purpose. The eggs should be collected on the farm twice a day and immediately put in the coolest place available. With this system there would be no difficulty in collecting and packing, and on the price obtained a bonus could be paid to the suppliers. Under this system there would be a big percentage that could be shipped to London. Probably when farmers realised the necessity for taking care of their eggs 70 or 80 per cent. would be suitable for export, and would fetch a good price. Unless some such scheme was brought about the eggs from the whole of the mallee districts would only be fit for pulping, and would fetch the lower prices. Mr. Shannon also addressed the meeting. (Secretary, Mrs. Cabot.)

PENOLA.

The Kitchen.—The following paper was read by Mrs. F. Kidman (Hon. Secretary) at a recent meeting of the Branch:—"The kitchen should be a bright and airy room, with enough space for the work that has to be carried out in it. The importance of a bright kitchen should be carefully considered when choosing a house, and special thought should be given to it. Sometimes an unavoidably dark kitchen can be made brighter by having the outside wall painted white, or a light color. Besides a cheerful aspect, there are several other points which must be attended to. Ventilation must be good, not only on account of those who have to work and live in it, but also for the benefit of the whole house. With a badly ventilated kitchen the fumes of cooking will spread to where they are not wanted. In addition to a door and a window, it is sometimes a good plan to have a ventilator put in the wall above the height of the window. To carry off the steam from cooking, whenever work is going on in the kitchen, the window should be a little open, even in winter. The sanitary arrangements must also have particular attention, and there must be a plentiful supply of water. As regards the position of the kitchen, it should be within easy reach of the dining room, and yet so placed that the odours of cooking do not penetrate to the other parts of the house. The pantry and store room should be near at hand to avoid unnecessary walking. The walls and ceiling of the kitchen—if plastered—can be whitewashed, or washed over with kalsomine or specially prepared paints, which can be had in a variety of shades. The woodwork in the kitchen should either be painted the same color or a darker shade. *The Flooring.*—This will be found to vary according to the locality—flags, tiles, red bricks, concrete, or wooden boards. Where the floor contains flags, tiles, or red bricks it needs no covering, because these are washed and a few rugs are all that are needed for standing on. With a wooden floor the boards soon become soiled and are difficult to keep in order. In this case it is better to cover them with some material that is easy to wash. Good, well-seasoned linoleum is the best covering for the floor, and one with a pattern is generally preferred, because it does not show the marks so readily as a plain one. *Fittings and Furnishings.*—The number of immovable fittings in a kitchen will vary considerably with the style of the house. They generally comprise dresser, shelves, cupboards, and towel rail, sink, and stove or range. The dresser is really a kitchen sideboard, and in most modern kitchens is fitted against the wall, and sometimes belongs to the house. If it has to be made to order, take careful measurement of the wall space available, and have it made to fit. The upper part is generally made with grooved shelves on which plates and dishes or the dinner service are generally kept, or the shelves may be used for jars with hooks along the edge on which utensils may be hung. It is advisable to have a few cupboards. These will be found very useful, because articles can be kept covered and protected from dust. Cupboard accommodation in the kitchen is most valuable, but, unfortunately, in many homes the supply is inadequate. It is advisable in a small kitchen to have a cupboard fitted upon the wall in which small store provisions may be kept. A recess or corner may be utilised for this purpose, and a carpenter can put a set of shelves with a door at a small cost. When time and labor are both precious, as much as possible should be kept under cover, in order to save continual dusting. If the kitchen is small, the most should be made of it by using the walls. Shelves are often a great convenience on the wall, but should only be erected the height that one can reach. High shelves in a kitchen are practically useless, and they are a harbor for dust. A strip of wood placed below a shelf with hangers attached will be useful for small utensils, such as gravy strainers, egg slice, &c. Do not drive nails into the wall. The sink should be fitted against the wall near a window at a convenient working height. The back of the sink, if not placed in a window, should be made of some material—such as tiles—which will not spoil with the splashing of water. A plate rack may be fitted alongside the sink, thus avoiding the drying of them. Then also there can be fitted a well-sloped grooved board, sloping towards the sink on which dishes can drain. In an ordinary kitchen there is very little movable furniture required, and it never should be fitted up with unnecessary articles; an important article being the table. This should be as large as is convenient to the room. Ample table room will considerably simplify kitchen work. It should be made of plain wood and a convenient height to work, and one that is steady on its legs. Preference should be given to a table with drawers. A piece of light linoleum or oilcloth may be put on table with the assistance of a few tacks, and will save a great deal of scrubbing. But care must be taken when oilcloth is used not to put anything hot on it. The arrangement of the kitchen window depends mostly on the style of the house. As a rule a short muslin curtain across the window is all that is required. A strong washing muslin is best. If the window is a large one, a pretty cotton casement cloth or linen will add very much to the appearance of the room. Woollen draperies must never form part of the furnishings, they hold the odours of cooking and are not healthy. *Kitchen Utensils.*—It is impossible to enumerate the number of utensils required in any house. This may be determined by the style of house and the accommodation there is for keeping things, the number in family and their requirements, and also upon funds at disposal. Whatever is bought should be good, and as simple in construction as possible. Well-made cooking utensils will last a life time, while an inferior class of goods is never cheap. A little extra outlay for goods will pay in the long run. Cheap tin goods rust and quickly rose shape, and thin enamel is always false economy. In most circumstances it is best to buy only just what is necessary to begin with, and gradually add to the supply as the occasion demands. It will generally be found that the better the cook the less utensils required. *Kettles.*—This generally depends on the kind of stove used. Block tin, wrought iron, copper, are all good and all are easily cleaned. Kettles that boil over are troublesome. One of the inventions in the kettle line is the whistling kettle, which gives a shrill whistle when the kettle has boiled and summons one to the spot. A good clock must not be forgotten when furnishing the kitchen—either one to hang on the wall or a good alarm. *Cleanliness of the Kitchen.*—These are two of the most prominent factors in the management of the kitchen. The old rule, "A place for everything and everything in its place," must be adhered to if order is to reign in this department, and it may be taken as a fact that if it does not reign in the kitchen it will not apply anywhere else in the house. It is very important that the kitchen be well arranged to start with, and that provisions and utensils, &c., be placed as near as possible to the place where they are to be used and handled. This saves unnecessary walking. Strength is often wasted in taking journeys which may be avoided. It requires some thought to arrange everything comfortably and conveniently, but with a little trouble this can generally be done, and the actual labor of cooking will be lightened to a considerable extent. No good work can be done in a muddle, and it is generally found that good cooks make less mess and use the fewest dishes. Where cooking is going on there must always be a cleaning up at the same time, for when the making of one dish is finished, everything for which there is no further use can be put away before another is started. Often a small washing up can be managed, and thus a big one at the end avoided. The kitchen and all that it contains must be kept scrupulously clean. This is imperative, both to health and comfort. Cleanliness is one of the attributes of a good cook. It ought, therefore, to form the ground work of all training, for without it there can be no good results where cooking is concerned. Not only must the kitchen have its weekly and daily cleaning, the utensils must also be kept in good order. 'You can judge a workman by his tools' cannot be better applied than to a cook, because no woman who has any pleasure in her profession would put up with an untidy kitchen or dirty utensils. The cleanliness of both should be her special pride and care. The cleaning of the kitchen can be accomplished in one day, or by degrees, as is found most convenient. If the kitchen is a very large one, the latter plan would be the better of the two, the work is the less obtrusive, and it does not upset the household so much as a big turnout would do. The stove and flue may be done one day, with the scrubbing of floors and tables to follow, the cupboards and windows another day, and so on. This is entirely a matter of arrangement, and must be planned to suit the ways of each individual household. The walls should be dusted. Tie a duster to the head of a broom. As a rule the kitchen requires a good scrubbing once a week, other days it must be swept over and washed as necessary. Linoleum should not be left wet. Windows—to clean these start at top and work down. Tables and cupboards—an effort should be made to keep these as white as possible; when cleaning a table do not forget the legs. *Saucepans.*—As soon as a saucepan is finished with it should be filled with water and left to soak until time of cleaning. Care should be taken not to pour cold water into hot enamelled saucepans, there is always a danger of cracking the enamel lining. Saucepans should be cleaned as soon as possible and only soaked overnight in special circumstances. The method of cleaning depends on the kind of saucepan. If iron or enamelled pans become burnt, boil with a little soda and water before cleaning. Soda must never be used with aluminium. New saucepans should be filled with cold water and brought to the boil before being used. *Cake tins* should be washed frequently. If they have been lined with paper, a good rub with a dry cloth or a piece of paper is all that is necessary. When they do require a washing, see that they are thoroughly dry before being laid away, they are very liable to rust. A very good plan is to put them on a rack above the stove or in the oven for a while. In fact all tin goods should be dry before putting away, also the mincing machine. After a pudding cloth has been used it should be thrown into hot water to which a little soda has been added. Let stand half hour and then rinse until no trace of soda water remains. Dry and put away until required for further use. A pudding cloth should only be used for its own special purpose. If the above process is not enough to clean it, it may then be boiled in a saucepan of water; the use of soap and soap powder being avoided. Pie dishes that have been stained and burnt in the oven may be cleaned with the use of a little salt. With regard to dish cloths, these are best made of some open material, such as thin old towelling, or cheap canvas-like material. Some people prefer a mop or dish brush, and both are useful. At the end of the day all kitchen cloths which have been used and soiled should be washed in soapy water with a little soda, rinsed, and hung up to dry. At the end of the week they should be laid aside to have a more thorough washing and boiling with the rest of the household linen, and a fresh supply put into use.''

WARCOWIE (Average annual rainfall, 11.42in.).

August 9th.—Present: 11 members and four visitors.

KEEPING CHILDREN EMPLOYED.—Mrs. A. F. Crossman read the following paper:—''Keeping children employed is a big problem at times, but what to get them interested in depends on the children themselves, what one likes another dislikes, and no two as a rule are just alike. The small child should be encouraged to make its own fun or amusement and not be running to mother with, 'What can I play with?' all the time, there should be quite a lot of interest in things outside for the average healthy child. Then for the little chap the handy man about the place can usually manufacture a cart with a coat of paint—it is usually hailed with joy. The child can be taught to bring mother a load of wood with this, and will think it fun until the novelty wears off, but with patience the child will, as he grows older, get into the habit of doing it and so in time be a little help. Then too, there are usually the cows to be brought in on most farms. If the cows are quiet and will not rush it does not hurt the older lad to do this providing they are within sight of the house or the child knows his way exceptionally well. They usually gain confidence to go further as they get older and most boys like doing things like that because dad does them. If children are able to attend a school they usually have their days full, and it need not worry mother what to give them to make the day pass happily. The little girls will often be very fond of dolls, and with one or two inexpensive ones and some pretty scraps of material be very busy indeed, and most enjoy joining in the boys' games as well. If girlie shows skill with dressing her dolls encourage her to make little dresses for them. A swing is also an inexpensive pleasure to both girls and boys, also a skipping rope for girls—they may wear their boots out but they will be healthy and happily employed.''

Mrs. G. Hilder read a paper on the same subject:—''Children, like adults, are quick to respond to suggestion. It is always wise to get their point of view as well as your own. When they ask questions, always try to explain as well as you can, as their minds are constantly developing. Give the children a pencil and paper; this helps to develop their brains and keep them occupied. At the table is one place where you can train them in their manners and in being polite, ask them to pass things to you, also to fold their feeders and serviettes. A very good present for children is a little wash tub and scrub-board, which can be bought for a few pence. On washing days give them a few tiny things to wash and make them do them properly. For a boy, a small wheelbarrow or a little watering can is useful. Bringing in the wood, gathering eggs, feeding the fowls, and little odd jobs about the home keep the children employed as well as helping mother. Always praise children for helping, although you may have to do it again. Do not let them see you doing it as they are very easily hurt and will not be so eager to help again. Children's temperaments differ. What one child will do quite easily another needs a little persuasion.''

PROGRESS

If you contemplate the future, as we all can and do, you must gather some conception of the enormous progress that civilisation will inevitably make within the probable period of your life.

You must realise, too, that such progress will be the sum total of all individual endeavours. Thus you will realise, no doubt have already accepted, your own part in this great forward movement, which is progress. If you are to play your part valuably you must not be a drag upon any other section of the community, but, in one respect at least, you can provide against this.

The Savings Account will help you build your career, help you to independence, and therefore to a useful place as a citizen. Very little money is required to start an account, which will cost you only the decision to open it, and to faithfully maintain it for your own, and, therefore, for the general national welfare.

Commonwealth Savings Bank of Australia

GUARANTEED BY THE COMMONWEALTH GOVERNMENT.

The same subject was dealt with by Mrs. A. Avery in the following paper:—"It is rather a difficult thing on the farms in the early stages of our children's life to find sufficient occupation of various kinds to keep our children employed without the employment being made too monotonous, so by the time the child has left school it is sick of the farm and all it contains. Children in the towns have so many more advantages than those on the farms, and parents should do all in their power to make farm life more attractive and less of the drudgery that it can be if no interest is taken in any other outside life. This also tends to make the views of our children narrow and one-sided. There are many jobs our children can do from the earliest of their lives that help mother and also help to keep their minds occupied and fill in their time; such as keeping the wood and chip box supplied for lighting the fire in the morning. This task should not be made an over-burdened one, as the small child should not be allowed to carry too heavy pieces of wood or drag heavy loads, nor carry the chip box too full and heavy. Then there are the eggs to be gathered. Teach the child to count as soon as it is old enough and then it can tell you how many eggs have been gathered. Then there are generally pets of various kinds on the farm. Give to the child one of these to care for and feed; this teaches them to love and look after the animals and to learn that animals require looking after the same as human beings. There is nothing more cruel to me than to see an animal or bird that is not properly cared for and looked after, especially when they are shut in cages or tied up. As the children grow older, watch closely for whatever occupation they develop a greater liking for in the various occupations that are given to them, and when old enough to do so, give the child a trial of that occupation and then the proceeds from such, if there are any, can be banked and used when needed for something else. Give the child a broody hen to set and look after. When the chicks are hatched teach them how to feed and rear the chicks and give to them some of the chicks they rear for themselves. These they may dispose of or keep for further profitable uses, but if done this way it will encourage them to try again, and when there are any returns these can either be used for enlarging the number of poultry or placed by for some other good use. If they have a tendency for a garden give them a corner and let them have a try with a few flowers and then give them some vegetable seeds. If these are a success let them sell some and with the proceeds buy some more seeds and try a larger plot. I do think the children on the farms to-day are given sufficient encouragement to carry on; too often the parents err by taking all the proceeds after the child has helped in a fairly large way to make the returns more profitable. If the children help milk the cows, give them either a calf, from which the proceeds should be banked for them until required, or give them some return from the cream cheques or butter that is sold. This subject deals with various occupations of the farm, but there are times when our children have not any liking for the farm or any of its occupations, then I would strongly urge that the parents endeavor to educate the children to the best advantage for the occupation they mostly develop a greater liking for, pointing out to the child that when it is old enough and sufficiently educated to earn a salary of its own, it should endeavor to return a small amount to its parents if it is needed for the help that was given it when it was not able to do for itself. Let the children join in the sports of the district and give them all the advantages of learning to do things, whether it be sport or work. Do not indulge in either to excess—work can be made too much a drudgery very easily and sports become very monotonous if overdone. Above all, in whatever tasks you undertake, teach the children to do it with a will and it will be done thoroughly." (Secretary, Mrs. A. Crossman.)

YURGO.

July 18th.

GARDENING.—The meeting was held at the residence of Mrs. Jarrett, who read the following paper:—"To make the garden a success a good fence which is fowl and pig proof is most necessary. If the men on the farm realised the comfort and happiness the women folk derived from a garden with its bright flowers and vegetables, the work of putting up a strong fence would not be a serious consideration. Nothing gives the home a brighter and more home-like air than a good garden. All vacant ground should be dug up and well limed and left in its rough state for a week. Then apply and dig in a good dressing of well rotted stable manure. All weeds must be kept down. They are great robbers of the soil, check the seedlings, and use up the moisture, and keep the sunlight from around the plants. Always hoe after watering, do not allow the soil to set firmly, it will crack and allow moisture to escape. The winter garden does best in most parts of the Mallee. Sow vegetable seeds in January and plant out seedlings as soon as big enough. It is most important to have the ground well prepared before planting out seedlings. See that plenty of rotted manure has been added and the soil brought to a fine tilth. Watch the seedlings carefully. It is not necessary to have large seedlings, but they should be strong plants. Use liquid manure to force them on, but see that the soil is damp before it is applied. Lettuce must be grown quickly to be a success. Use plenty of liquid manure and never allow the soil to dry out. In fact, all vegetables are the better for having been quickly grown. Do not overcrowd the plants, the sun should always be able to shine between the plants and care should be taken about the rotation of crops. Beans are usually difficult to grow, but if "Climbing Epicure" is sown in September and properly looked after success will be assured. Plant behind a broom brush fence away from the north winds, then when the plants have the beans ready to set, start watering with sulphate of ammonia every three weeks, using three dessertspoonsful to a petrol tin of water. Well water the plants, taking care not to wet the foliage with bore water. Onions do exceedingly well in the sand, and if pulled correctly can be hung and kept for months. Beans and peas are two of the best nourishing vegetables and can be grown. Spinach is easily grown and should be given to children. Carrots, grated, make a delicious sandwich for school children. Maize makes a good break-wind, but allowance must be made for its roots if other crops are planted near it. It makes good cutting for green feed for poultry, the cobs are very sweet and can be used in the home. The dolichos makes a splendid break-wind. As to flowers, this depends on how much time and room one has. However small or plain a home may be, some flowers give it a touch of refinement. Bulbs grow well in the sand, and if some are planted in pots or tins, they can be lifted while flowering. The same applies to many other plants. Carnations are easily grown, but they do not last very long on bore water. However, they can be kept going by striking fresh slips every year. Lantanas make a wonderful show and are quick and strong growers. A good plan is to get tree seeds of all kinds and raise trees for beautifying the homestead. Almond trees are both pretty and ornamental, the almonds being exceptionally useful. Sunflowers grow easily and will give the place a touch of brightness, and the seeds are useful for poultry and birds. Gardening has many bright sides, and if country folks only realised the joy of it they would try even if their time is limited." (Secretary, R. Sanders.)

MUNDALLA AGRICULTURAL BUREAU.
FIRST AID -- VETERINARY CABINET

The illustration above shows the First-Aid Veterinary Cabinet declared open for use by Mr. F. C. Richards (Assistant Secretary of the Advisory Board) at the Annual Meeting of the Mundalla Branch of the Agricultural Bureau. Mr. W. T. Herring made the cabinet without charge from timber donated by the Secretary of the Branch (Mr. H. Ross), in whose care it will be placed. In consultation with officers of the Stock and Brands Department and Mr. R. Wiese, of Mundalla, an excellent assortment of first-aid veterinary medicines and drugs was purchased by subscriptions from members of the Branch. The chest also contains various instruments, and these will be added to from time to time. It is proposed to allow members of the Branch to purchase the medicines at wholesale rates. The foundation of this chest is an excellent idea and one which should commend itself to other Branches of the Bureau.

BLYTH (Average annual rainfall, 16.76in.).
July 22nd.—Present: 12 members.

Pig Raising on the Farm.—Mr. W. O. Eime read the following paper:—"If a farmer intends going in for pigs to any great extent, it pays to breed suckers, to buy them means that one cannot always get just the desired breed, and at times the price is too high. Suckers are not always as cheap as at present. I favor the Tamworth or Large White York sow crossed with a Berkshire boar, the main point is to get a good sow which will produce large litters, nothing under seven should do. If a sow produces less than seven, fatten and send her to market. A good cross, which I have found the most economical pig to rear and easiest to fatten, is the Gloucester Old Spot crossed with a Berkshire and that sow put back to a Berkshire. I have known pigs of this cross to dress 140lbs. at four months old. Generally speaking, the right class of pig should net the farmer £2 when five months old. *Feeding.*—A sow with a litter should receive a gallon of crushed corn with a little linseed and crushed oats, and about 1gall. of skim milk three times a day. This ration should be increased if the litter is very large and as the pigs grow. Most young pigs will start to eat when about four weeks old. The Large White I have noticed eat younger than any other, and the Berkshire is about the slowest at starting to eat. Wean when the pigs are about eight weeks, and wean gradually. Shut them away from their mother during the day and leave them together overnight for a few days, then for about two weeks give them crushed grain and skim milk, and after that put them with the other pigs on the self feeder, plenty of skim milk, and crushed wheat and as much green grass or lucerne as they care for. Crushed malt barley is very good, but wheat is without doubt the best fattening feed. I favor small paddocks and letting them graze. Dry sows do quite well on pasture; charcoal and a little ashes is good for them, also a little phosphate. It is necessary for them to have a little mineral each day. A good lick is 6 parts salt, 1 sulphur, 4 charcoal, 1 Epsom salts, 8 superphosphate. The chief trouble is that they do not only lick at this mixture, but they eat it, and it keeps one busy mixing it. The yards and sty should be well protected from the cold winds, and I favor a fair sized run with a good straw stall for shelter, where they can sleep on the sunny side sheltered from the wind. A young pig that has a serious setback will never pay to fatten, and my advice is to sell it. The best size to market pigs is when they will dress from 120lbs. to 150lbs. The man that has the right article will always get a reasonable price. More is paid per pound for baconers than any other class of pig, and a pig dressing 150lbs. of the Tamworth-Berkshire cross is ideal for bacon or ham. If a farmer does not favor crossbreeds, stick to the Berkshire, that is the only pig worth while of all the pure breeds. I am just trying a Large White York-Berkshire cross, and as far as growing quickly it seems as good as any other, but one must not lose sight of the Tamworth, which is a hardy mother and does not mind the heat or cold, and they are without doubt the best for foraging for their food. The farmer who milks a few cows should rear a few pigs every year." **(Secretary, L. Mugge.)**

splendid milk-producers and do not affect the flavor of the butter. Most farmers neglect growing Cape barley for the benefit of their cows; it is a better milk producer, and is much preferred by the cattle to malting barley . When hand-feeding, give oaten chaff with bran and crushed oats, adding a handful of bonemeal once a day. A box of equal parts of salt and super or bonemeal should be placed where it is accessible to all cattle. This is a most important factor in keeping the cows healthy. If possible water should be in every paddock where cows are pasturing. This is not only of great benefit to the cows, but is a great save to the farmer. On winter nights cows should have the benefit of a straw stack for shelter. The cow is a nervous animal and the strain of producing milk twice daily for perhaps 10 or 11 months of the year is a big drain on her system. Therefore every care should be taken in handling, feeding, and milking of the cows. For a fair sized herd I favor de-horning. This is best done when the calf is a few days old, by rubbing caustic potash on the horn buttons. Dehorned cattle are much quiter and more contented and are not harassed by one another, therefore they have a better chance of producing more. If all bulls were de-horned it would save dozens of accidents and possibly many lives. A few emergency medicines should be kept in case of sickness. One lb. Epsom salts, treacle 1lb., and ginger 2ozs., is a good drench for impaction or stoppage. For retention of afterbirth give two pints strong coffee with 1lb. Epsom salts, adding 1oz. sulphur. A few homoeopathic medicines are often handy, especially powdered nux vomica. Always keep a milk fever outfit on the farm, heavy milkers are apt to go down with this complaint. Inflation of the udder is the only treatment for this malady; take care and sterilize the needle and smear with vaseline before use. For mammitis apply hot fomentations to the affected quarter, then rub with warm camphorated oil. In the case of cows having pox on the teats, use turps 2 parts, olive oil 1 part. This can also be used for cut teats. A farmer who has good milking sheds where all cows can be fed in mangers and can be milked where they feed has a big advantage over those who bail each cow separately as it is milked. The floor of the shed should be bricked. These improvements are not only a great convenience, but a save in time. Exports of butter this season showed an increase of 2,150 tons, being 188 per cent. greater than the previous year. As regards decreasing costs of production, most farmers have been compelled to cut down expenses as much as possible, and the factories should try their utmost to decrease the charge of manufacturing. Even one farthing a pound reduction would mean over £12,000 more for the dairy farmers of this State. Producers should use every effort to keep the cream at choicest quality all the year round; that would help manufacturers because it would reduce the need for special treatment of lower grade creams. I favor a 50-test for the cream, because it is much easier to keep it in good condition. Always send the cream twice weekly to the factory, and if possible three times a week in summer.''

In addressing the meeting on ''Recreation on the Farm,'' Mr. Roberts stated that many men considered sport was unnecessary on a farm, and if indulged in, the farm could not be worked properly. He maintained that the crop yields of farmers who took part in sport in the district were equal to, if not greater than, the farmers who worked on their farms every day of the week. He considered sport should not be indulged in during the busy times such as seeding and harvest, but during fallowing recreation could be indulged in by both the male and female with advantage if they chose a good class of sport. It taught persons to take defeat in the right spirit and also to recognise a feeling of goodwill and fellowship among those with whom he or she came into contact. The social side of the question could not be over-estimated. Persons kept fit by sport were able to work ably, and were hale and hearty in old age. It also served as a character builder, which always helped a person through life. Sport was necessary on a farm, and in times of financial depression, &c., helped one to forget worries and to look at the bright side of life. In discussion, Mr. V. K. Oliver stated that since taking part in sport the half-day loss was not noticed; it assisted one to work enthusiastically. (Secretary, C. Currie.)

WIRRILLA.

May 15th.—Present: 16 members.

Care and Maintenance of Tractors.—Mr. A. Woods read the following paper:—''The tractor will respond to the treatment it receives just as surely as the horse, only in this mechanical power unit the results of care or abuse are more immediately noticeable, and the effects are more serious. The proper treatment of tractors is, therefore, essential to their long life, reliability, and to their economical service. On starting up the engine should be run on motor spirit until it is thoroughly warm before changing over to kerosene, and during the actual working the water in the radiator should be near boiling point—too much heat appears to cause a loss of power. The too early change over from petrol to kerosene tends to give crankcase dilution, and the running of an engine too cold does not allow the kerosene to vaporise sufficiently and give its fuel economical power. Since petrol is more expensive than kerosene, every effort should be made to warm the tractor on starting quickly by covering the radiator, this should also be done when running on light loads or in very cold weather to maintain the temperature of the water and help to reduce crankcase dilution. *The Air Cleaner.*—If the air filter is not kept in good condition particles of dust will enter through it into the mixture and into the cylinders, acting as an abrasive and causing rapid wear of the piston, rings, and cylinder walls, making rebores much oftener. Particles of dust also assist in the formation of carbon. Dirty filters also restrict the inlet of air and tend to give too rich a mixture. *Draining Crankcase.*—Since the oil in the crankcase must carry out so many duties, it is essential that this should be of high quality and kept in good condition. Owing to dilution and gradual accumulation of foreign substances, such as grit, the crankcase oil requires changing from time to time. The period between changes should not exceed 50 hours on kerosene and 100 hours on petrol—shorter hours would be beneficial to the life of the cylinder block and piston rings. Always keep the level of the crankcase oil well up, but do not overfill. When draining the crankcase kerosene should never be used for flushing purposes, as this may be caught in the pockets of the casting and pre-dilute the oil. The crankcase should only be drained when the engine and oil are thoroughly warm, because at that time the oil is well stirred up and will flow freely, thus allowing all the particles of foreign matter to flow out with the oil before they have time to settle at the bottom of the crankcase. The chief foreign substances that enter the crankcase oil are five in number—kerosene, dust, water, carbon, and steel, even with the protection of air cleaners and filters, the velocity of the inrushing air is so high that some of these particles of dust find their way into the engine. Once inside the engine it quickly mixes with the oil and accumulates on the cylinder heads and around the valves. This abrasive dust, mixed with oil, cuts much faster than would the dry dust that floats in the air around the engine. The air breathed in by an engine has a certain percentage of moisture, more so, of course, in damp climates than in dry. For each pound of kerosene burned there is about a pound of steam formed. If the crankcase is not warm some of this steam vapor will condense, forming water. Analysis of used crankcase oil often shows that it contains as much as 40 per cent. water. If you hold a glass tumbler over the exhaust pipe you will notice a rapid collection of water drops from the exhaust, so that it is essential to keep the engine at the right temperature, and frequently drain the crankcase. Do not neglect this important job if long life and low repair bills from the tractor are desired. A recent laboratory analysis of an oil after only 10 hours of operation showed that the lubricant contained 20.2 per cent. kerosene and 3.4 per cent. foreign matter. Such a diluted, dirty oil soon brings engine trouble and costly repairs. *Points to be Observed.*—(1) Change oil frequently, not over 50 hours on kerosene and 90 to 100 hours on petrol. (2) Drain crankcase when engine is hot. (3) Use correct grade of oil always, and keep to proper level. (4) Clean oil screen every six months. (5) Keep oil and air purifying devices clean. (6) Replenish oil frequently and in small quantities rather than large. (7) Avoid rich mixture adjustments of carburettor. (8) Keep ignition system in order; its efficiency affects dilution. (1) Do not drain crankcase when it is cold. (2) Do not flush with kerosene. (4) Do not overfill, excess of oil causes dirty plugs and increases consumption. (4) Do not continue to operate the engine when it continues to misfire, it may be a broken valve, and much damage will result. (5) Do not idle engine unnecessarily. (6) Do not race the engine, especially when starting up cold. (7) Do not use heavier oils because engine is warm, oil will never take the place of metal. (8) Do not forget oil is cheaper than repairs. (9) Do not forget to grease wheels and rollers, stearing gear, &c., at least once a day on caterpillar tractor, and use only heavy body oil, such as transmission oil. They were never made for grease; a very heavy oil is needed in harvest time. (10) Use only fresh, clean rainwater in the radiator, it is not advisable to use dam, well, or creek water if possible, but when this cannot be helped the radiator should be drained every few days with soda to clear out the sediment which collects in the tubes and water jackets of the cylinder block and may cause over-heating. (11) Always cover up the tractor at night, this will make for easier starting on cold, damp mornings, and also preserve the paint. A tractor four years old, which has always been covered up when idle in the paddock and at night, will look as new as one two years old which has never had a cover on it at night. Tractors are very useful pieces of machinery, and they have come to stay, but they cost money and cannot be bred like horses, so if given fair treatment they will give good results. Treat them as you would a team of £50 horses and they will not fail, and will do the work in half the time, and 24 hours a day if we want them to.''

Care of Horses.—The following paper was read by Mr. A. Evans:—''When bringing horses in from the stubble to prepare for seeding, do not give them a big feed and expect them to go into hard work. Bring them on to the feed gradually.

links made of ⅜in. iron about 3in. to 4in. long are very handy if working on rough ground. Should a bridle chain of the plough or cultivator break, it can be repaired in a few minutes. With the saw and hammer many carpentering jobs can be done to the sheds. (Secretary, S. Chynoweth.)

BRENTWOOD (Average annual rainfall, 15.54in.).

August 4th.—Present: 16 members and four visitors.

POULTRY AS A SIDELINE.—Mr. L. Darby read the following paper:—"The three chief sidelines on the average farm are sheep, cows, and pigs, but poultry can be made quite as profitable as any of these, providing the right breeds are kept and they are given proper attention. The breeds I would suggest keeping are White Leghorns, Black Orpingtons, and the new Dutch breeds, Welsummers and Barnevelders, are worth giving a trial. They are good layers of a large egg and are also splendid table birds, non-sitters, very hardy, and easy to rear. The average farmer should keep at least 150 laying hens. The houses are the first things to consider; these should be dry and free from draughts. All poultry should be locked up at night, and then there will be no trouble with foxes, and do away with the nuisance of them roosting on implements, etc. I advise feeding mash in the morning with grain at night, and green feed and meat meal with plenty of clean water and shellgrit always before the birds. The green feed is our biggest problem during summer. If it is possible to grow a patch of lucerne, the egg yield will be increased. The best time to hatch chickens is from August until October. If hatched during these months, the pullets should be laying when eggs are dearest. The incubator is the best for hatching. The chickens can be given to broody hens if they are available; if not, a very simple brooder can be made for very little cost and heated by an ordinary lantern. The cockerels should be separated from the pullets as soon as they can be picked, penned up, and fattened ready for market. It is a good plan to mate some of the best second year hens with a cockerel of a good laying strain. Eggs weighing under 2ozs. should not be hatched from. Hatch only from the 2oz. egg and larger and it will be possible to breed up a flock of hens that will lay a larger egg. All hens should be passed out at the end of the third year: after that the average hen does not pay for its keep. The poultry houses should be cleaned out frequently and the floors dusted with lime to keep down disease. A little Condy's crystals should be added to the drinking water. Roosts should be oiled regularly to keep down tick, red mite, and scaly leg parasites. Old car or tractor oil mixed with kerosene is good for this. All eggs should be kept infertile except those used for hatching, thus helping to establish a better export trade, which is so essential to Australia. All eggs should be kept clean, gathered daily, and marketed as early as possible. Ducks will lay more eggs than fowls, but I would not advise going in for them in large numbers. A few geese and turkeys may also prove profitable to sell at Christmas. With grain at a very low price as it is now, poultry can be made quite a profitable sideline, even if eggs are a low price. (Secretary, E. Carmichael.)

WESTERN DISTRICT.

GREEN PATCH (Average annual rainfall, 26.56in.).

August 11th.

Mr. A. T. Cowley read the following paper on "Fallowing":—"From time immemorial ploughing has constituted the foundation of all working of land intended for the growing of cultivated crops, nor have the methods employed in ploughing varied greatly, so far as we can learn, until quite recent years, when modern methods and modern implements have resulted in a great variety of ways in which land may be worked or cultivated, with ploughing or breaking up and turning over of the surface to the desired depth, as the commencement of each period or cycle of working. By fallowing or breaking up the ground in winter or spring prior to the season in which it is to be sown we allow time for a great variety of workings and treatment of the land between ploughing and sowing, varying in different districts according to the nature of the land and climatic conditions. The purposes of fallowing common to all districts may be said briefly to be to rest the land from continuous growing of crops (a principle found as far back in history as the law of Moses), to eradicate weeds, and to allow time for treatment calculated to improve the conditions and fertility of the soil. Naturally we expect to harvest a more profitable crop from land that has been fallowed than from land not so treated. In calculating our profit we must, therefore, consider the cost of fallowing, and perhaps there has never been a time when it was more necessary than at the present to calculate as accurately as possible the cost or what we shall lose by fallowing, and the advantages, or what we shall gain by it. If we were to go no further in our calculations than the two years involved in growing a crop on fallow, we should be forced to the conclusion that under present conditions fallowing could not be made to pay. In other words we cannot follow a two-year rotation of fallow and wheat, or any other cereal which we may grow. On the other hand, we shall have to consider how long a period of rotation of cropping and grazing we can follow before we shall be at a loss by not leaving the land idle, or under fallow for one season. Upon the correct calculation of length and use of the rotation period, following upon the correct working and treatment of the land during the fallowing and cropping period, will depend our ability to gain the greatest profit possible from the land, under the varying conditions over which we have no control. The chief of these factors being weather conditions, and the market values of our various products, whether in the form of crops or livestock or their various by-products or sidelines. However, the purpose of this paper is not to deal with crop rotation or other uses of the land, but in view of all possible uses in conjunction with cereal growing we shall conclude that at least a portion of our land should lie out to fallow each year. I shall endeavor to deal briefly in a general way with some of the essential points to be taken into consideration in fallowing. Beginning with the initial breaking up of the ground we may consider the time of the year when this can most profitably be done. Whether we plough as early as possible, before weeds get a strong start and at the same time allow ourselves the longest possible period for subsequent cultivation, or whether we can more profitably run sheep on the land intended to be fallowed until late in the winter or early spring, thus allowing the sheep paddocks proper to become well grassed and so increase our sheep-carrying capacity, and still allow time to work the fallow fairly effectively, and without too seriously discounting the value of the subsequent crop. When a large area has to be fallowed and it is desirable to get all the land broken up early, it is possible under certain conditions to resort to the practice of summer fallowing, when the land can be broken up before seeding, following a summer rain. This is usually done without ploughing, and in this respect is an exception to the rule which, however, cannot be repeated—that is to say, it can be done only on land which has been ploughed in the preceding working. It is usually done with a spring tine cultivator which can be run over a large area quickly after rain, thus covering several times as much ground as could be ploughed while the moisture lasted, and by forming a mulch retaining the moisture long enough to enable another working to be given immediately with the same implement. This double working, under certain conditions being practically equal to later ploughing, allows of subsequent workings being given similarly to those employed on the later ploughed fallow. Winter fallow may be ploughed deep or shallow with pointed or plate share, or disc, according to requirements. Also "early" or "late." Under the latter headings it is generally understood that the earlier the ploughing the greater the depth. Other considerations also govern depth. Land described as heavy may be ploughed to a depth of 4½in. or more while light land is usually broken to a depth of less than 4in., and often less than 3in. Reverting to the question of time, it is generally understood that early ploughed fallow—commencing, say, about the middle of June in most districts, gives the best crop results, while a later start with the plough may give some advantages in the form of extra sheep feed, as already indicated. Subsequent working of fallow is calculated to serve various purposes. It may serve to improve the texture of the soil, to consolidate the subsoil, to aerate and sweeten the surface, control the moisture content within certain limits—that is, in a too-wet soil condition the working should be done with a view to the prevention of water logging, while in the greater part of the farming land of the State the object is to retain all possible moisture by keeping the bottom fine and closely packed while the surface is kept fairly rough and loose to form a mulch and retard evaporation, and at the same time to lessen the danger of drift to which some of these areas are liable if finely worked on the surface. A second reason for working of fallow is the destruction of all weed growth. Sheep should be used in conjunction with proper implements to assist in fulfilling both of these purposes, and also, in summer, if weeds persist in starting owing to the moisture retained through spring cultivation, or from a summer rain the sheep themselves will benefit greatly by the nibble of green thus provided when all other feed is dry. To go further into the question of the working of the fallow we may profit by discussing the work of some of the principal implements to be used. The plough may be required to have a pointed share for heavy or tough land, while a plate share is generally favored for light or medium soil. In either case mould-boards are required to be of such size and design as to completely turn and pack the soil. Too little attention is given to the latter requirement, as failure to place the turned soil firmly on the bottom to prevent the formation of cavities or air pockets, leaves a condition encouraging to the development of ''take-all'' in the subsequent crop. I regard the disc plough as an implement for use under special conditions only. I cannot speak from experience of possible uses for this implement in heavy land. In light soils the main uses are found in its ability to pass through, and effectively cut up, shrubs or rubbish that would choke another plough. In newly-cleared scrub land it is particularly efficient, not only in cutting through mallee or broom shoots, but also in shearing them off the stump and materially assisting in this ultimate destruction. Also in chopping up small tree roots lying near the surface where these are sufficiently numerous to be troublesome to any share or tine implement. For ploughing under ordinary conditions, I do not consider that the disc can compete with the share and mould-board plough. For subsequent working of fallow, if ''turning back'' with a light skim plough is favored, the depth should be considerably shallower than the original ploughing, the purpose of all workings being to consolidate the bottom layer of whatever has been turned under from the old surface, and to keep open to sun and air, and prevent packing or caking of what has been turned up to the surface to ultimately form the tilth for a perfect seed-bed. The main advantage of the skim-plough is found in dealing with weeds of such a nature as will persist in growing unless turned completely under. The spring tine cultivator—or the combined drill and cultivator which is more generally used—will cover almost twice as much ground in the same time and with the same team as required for the skim plough, and with the exception of the tightest rooted varieties of weeds, leaves them lying completely torn up on the surface of the soil, and a few hours of sunshine will wither them up completely. Two other great advantages of this implement are:—1. That the finer particles of soil are run to the bottom of the working, forming an ideal seed-bed for the subsequent crop, and leaving the light loose soil and all rubbish on the surface which, where the conservation of moisture in the soil is of importance is of great value in assisting to prevent evaporation. 2. The spring tine lends itself more readily than any other implement to a combination with the seed drill. The slight extra weight involved not being any serious disadvantage when doing cultivation work, while the advantage of giving the final cultivation and drilling in one operation on fallow or any clean ground is a great consideration from a time-saving point of view when the crop is going in. Evenness of depth and covering of the seed is, I believe, more effectively controlled with the tine drill. On stubble or bushy land a disc drill is necessary, and where this is required some farmers may prefer to cultivate and drill separately, but I think these will be in a minority. I have not referred to the work of the scarifier, or heavy rigid tined cultivator as I regard this slower and heavier type of implement as a back number except in rare instances where circumstances may warrant its use. One implement of great usefulness and the cheapest of all to operate is a set of good harrows. For breaking down the surface of rough ploughing, giving the weeds an extra worrying after cultivating, running over the ground quickly after a shower when time will not permit of other working, for smoothing down before drilling, and for making a good finish and level surface after, have a good set of harrows always ready. However, harrows must be used with caution on land that drifts.'' (Secretary, C. Whillas, Port Lincoln.)

KYANCUTTA.

July 5th.—Present: 13 members.

Members were present from the Wudinna and Waddikee Rocks Branches. The paper read by Mr. D. Duguid, of the Wudinna Branch, was entitled ''Some Uses and Abuses of our Bureau.'' Mr. W. Hier, of the Waddikee Rocks Branch, read a paper, ''The Best Time to Start Fallowing in New Country.'' This caused a lively and interesting discussion. Mr. Shepherd, of Wudinna, considered that September was too late to fallow. The ground was then drying out, and liable to drift. Mr. Daniel did not agree with Mr. Hier's idea of keeping as much draught as possible off the plough, because he would like to pull out all the stumps possible at the first ploughing. Mr. Du Bois (Wudinna) thought that the fallow should be worked as much as possible, but did not favor too much use of the harrows. They should be used directly after fallowing to pack the ground. He also stated that in most years when there had been good early rains after harvest land ploughed early and left until the latter end of seeding had always given as good a return as fallow. Mr. Matthews (Waddikee Rocks) thought that in working the fallow the farmer should work only the flats between the sandhills, and then the ground would not blow so much. Mr. E. Dyke said he was very much against ploughing in stubble or dry grass, because it was very hard to consolidate the ground after doing so, but thought that if the stubble was not too thick, and had been well tramped over by sheep before being ploughed in, it should soon rot, and if sheep were turned on the fallow to keep the weeds in check they would materially assist in packing the ground together. After a good discussion, the general opinion was that it was as well to start fallowing as early as possible, and to so work the fallow as to avoid the possibility of drift. Where able, sheep should be run on the fallow to keep weeds down. (Secretary, J. Dyke.)

MANGALO (Average annual rainfall, 14in. to 15in.).

August 2nd.—Present: 19 members.

Farm Records.—Under the heading "Should Farm Records be Kept" Mr. F. Coles read the following paper:—"How can I make my farm pay? This is a question that is constantly passing through the minds of farmers to-day. Some say the answer is to keep cows, pigs, and poultry; some say reduce all taxation; others offer various different ways for declaring a satisfactory farm budget. No doubt relief could come from these avenues, but as with any business, so it is with farming, that there are general principles to be followed for the guidance of business on sound lines. Among the headings under which these principles can be defined are method, *i.e.*, manner of working the land, feeding of stock and management of stock, system, marketing, and records. How many members of this Branch can claim to be able to state at a moment's notice how many eggs their fowls laid for the year, or how many lbs. of milk their cows yielded over a given period, or how many lbs. of vegetables were produced from the garden? The man who keeps department records is able to look from day to day, or from year to year, just what was produced from a set of hens under certain conditions, or from his cows, or what weight of meat was consumed for rations on the farm. When a term of years has passed, he can, by his records of results, more easily enthuse his children to follow his example and business. The keeping of such records creates interest, ambition, and competition, and indicates which animals to cull, what departments need speeding up, and what scope there is for development. I believe that farmers who keep a continuous record of their production do so to advantage, and this is one channel which is deserving of more attention than it has been given hitherto." (Secretary, K. Nield, Cowell.)

WADDIKEE ROCKS.

June 27th.—Present: 11 members.

Curing of Bacon.—Mr. V. Matthews read the following paper:—"There are various opinions as to the best bacon pig, but the Berkshire and Poland China cross or the Berkshire-Tamworth cross will produce a good, streaky bacon. The colder months of the year are the best time to kill for bacon, because nearly the whole of the carcass can be used. A pig of about 180lbs. to 200lbs. is a useful weight, and after it is killed and cleaned it should be left to hang for 12 to 24 hours. A good sharp knife, a saw, and a chopper are necessary to cut up the pig. When the meat has set, first run the saw down from the tail to the nose. Cut out the backbone by chopping the rib bones close to the backbone; take out the backbone in one piece, cut off the head close behind the ears, and remove the flat pieces of lard from the ribs. Saw off the trotters, the front ones at the knees, and the hind ones at the hock joints. Cut off the hams for bacon, and leave the sides as long as possible. Cut off the shoulder close to the shoulder blade, shape the hams, and take out the bone down to the socket, sawing off the knob; this will help to cure the bone of the ham. Bone the shoulder and leave in one piece to cure. Cut out the rib bone from the sides, and level off the fleshy pieces with a knife. All scrap meat can be put into a sausage machine, or used in other ways. Treat the other half of the pig in the same manner. *Curing: Making the Brine.*—Obtain a clean pickling cask, sprinkle a thick layer of salt on the bottom, put into a pan about 6lbs. of salt, 3lbs. brown sugar, ½lb. saltpetre, mix well together and rub each piece of meat thoroughly with the mixture. Pack the meat into the cask, fleshy part upwards, and place the bacon sides on the top of the other meat. Allow to stand for about three days, and then drain off the brine and turn the meat. Make another brine by filling a clean kerosene tin bucket about three parts full of clean water. Dissolve as much salt as will float a fresh egg, add the brine previously taken off the meat, and bring all to a boil. Skim off any scum that may rise, and stand until thoroughly cold. When cold, pour over the meat, which should be turned every day, and the bacon should be left in the brine for about 14 to 16 days, hams perhaps a little longer. Rinse in cold water and hang until dry; then cover with linen bags away from dust and flies. *To Roll the Bacon.*—Beat the sides out flat with a rolling pin; sprinkle a little seasoning over the meat; then roll up tightly with a buckled strap to keep in position. Place several coils of bacon cord around the rolls about 1½in. to 2ins. apart, draw up tightly and make into half hitches to prevent slipping, and tie securely. Remove the snout and ears off the head and cut into six pieces; take out the eyes and brains and soak in salt and water for 12 hours. Obtain a large saucepan, and boil head until the meat leaves the bones; remove all the bones, and put into a dish and leave to set. When firm, it will be easily cut, and will make a very nice brawn.'' (Secretary, V. Matthews.)

WARRAMBOO.

July 12th.—Present: 15 members.

Tree Planting.—The following paper was contributed by Mr. F. Chilman:—''One of the first things to take into consideration when about to plant trees is the locality and the nature of the ground, also to note what trees are making the best headway. About a fortnight before planting dig holes about 2ft. square and 2ft. deep, and leave them open until ready for planting. If obtaining trees from a nursery, they will be packed in small pots, stand these in a tub of water for a few hours and allow the water to come half way up the pots. This will revive the trees and make it much easier to take them out of the pots. Always stand any trees in a tub of water when they reach the farm if they have been on the road for a couple of days. When taken out of the pots it will be noticed that the roots are in a round ball. Have a bucket of water handy, and gently break up this ball in the water, free all roots, and cut off any that are injured. They should then be ready to put in the hole. Have the soil slightly raised in the centre of the hole and spread the roots out all around, sloping them slightly downwards towards the side of hole. Fill in with soil, keeping all stones and pebbles away from the roots. Press dirt down firmly and then give a good watering to set the soil firmly around the roots and force the air out of the pockets. Some trees require staking. To do this always put the stake in the hole first, then plant the tree by it. The Sugar and Tooart gums grow reasonably well in sandy or limestone ground, providing any stones are removed from the hole. Where the stone is bad, it is a good plan to put in a charge of dynamite to shatter the stone and give the roots a chance to get down. Peppers do exceptionally well in sandy ground, also Tagosaste. All trees must be protected from stock until such time as the animals will not injure them. From personal experience I have found it better to raise the trees from seed, then they do not get a set back through being transferred from one district to another. Try to get the trees out early in winter—June for preference—then they become rooted before the hot, dry weather sets in. If stable manure is added to the soil see that it is well worked in, do not on any account allow the roots to come into contact with raw manure.'' (Secretary, E. Adams.)

YADNARIE (Average annual rainfall, 14.09in.).

July 12th.—Present: Eight members and four visitors.

I.C. Engines.—Mr. L. Tyler read the following paper:—''Engines other than steam are termed internal combustion (I.C.) engines. Whereas in a steam engine the fuel is burnt in a separate place, called a boiler, and the products of combustion carried by means of pipes to the engine, in an I.C. engine the fuel is actually burnt or combustion takes place inside the engine. Hence the term. I.C. engines are classified according to the fuel they use. A gas engine uses permanent gas which may be town gas from the public mains, tower gas produced in special producers, or waste gas from a blast furnace or coke oven. An oil engine uses kerosene, lamp oil, crude petroleum, or the like, which liquid fuels are usually volatilised by heat treatment in a vaporiser. The petrol motor utilises the spirituous products of petroleum which are vaporised at ordinary temperatures in a carburettor. An alcoholic motor uses the vapors of denatured alcohol and much resembles the petrol motor in detail. *General Construction.*—As a rule the cylinder of an I.C. engine is single-acting and open at the end nearest the crank, the power impulse being received at one end only of the piston, in order to avoid the use of a piston rod and stuffing box that might be injuriously affected by burning gases. The trunk piston consists of a tube closed at its inner end, and is coupled direct to the crank pin by a connecting rod, the piston thus forming cross head and guide. The clearance space at the closed end of the cylinder into which the piston does not enter is usually called the combustion chamber. In it are situated the inlet and exhaust valves for controlling the admission of the mixture and the egress of the products of combustion, a third valve being usually provided in gas engines, to regulate the admission of gas to the mixing chambers formed in the passage to the inlet valve. The valves, normally of the mushroom type with conical seats, are closed by springs and are opened inwards against the pressure of the gases by cams or a camshaft driven by gearing from the crank shaft. *Modes of Action.*—The three ideal modes of operation are—1. Constant pressure cycles. 2. Constant volume cycles. 3. Constant temperature cycles; and an engine working on one of these cycles may be either two stroke (Clark cycle) or four stroke (Otto cycle), and it may further be either single acting or double acting. The most important parts of an I.C. engine are the cylinder and water jacket; the piston connecting rod and crankshaft; the fly wheel; the valve mechanism; the governor (when fitted); vaporiser or carburettor (for oil and petrol engines); the ignition. *Cycles of Operation.*—In the great majority of I.C. engines the cycle of operations within the cylinder is completed in two revolutions of the crankshaft or four strokes of the piston and engines working on the four stroke cycle or Otto cycle are commonly termed. The camshaft of a four stroke engine naturally revolves at one-half the speed of the crankshaft since each valve requires to be acted once only during two revolutions of the engine. The four strokes of a four stroke cycle engine are reproduced. *Two Stroke Engines.*—To obtain a larger output of power from a cylinder of given dimensions and to secure a more uniform rotative effect, some I.C. engines are arranged so that a power stroke occurs in each cylinder at each revolution, as the cycle is complete in two strokes of the piston it is known as the two stroke cycle or Clark cycle. In the simplest form of engine working on this cycle, the piston, connecting rod, and crankshaft are enclosed in an airtight case which serves as a reservoir for the mixture. The engine is a two port two stroke. *Three Port Two Stroke Engines.*—To avoid the use of a non return valve in the crankcase, the three port motor has been introduced in which the mixture is taken by a third port in the cylinder that is alternately covered and uncovered by the moving piston. The piston controlled inlet port being so arranged that it is open to the crankcase when the piston is nearing the top of compression stroke. During the earlier part of the stroke a partial vacuum is formed in the crankcase and the mixture flows during the small period that the port is uncovered and covered as the piston approaches and passes the top of its stroke. The remainder of the cycle is as in the two port two stroke engine.'' (Secretary, E. Spriggs.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

KI-KI.

July 23rd.—Present: 10 members and four visitors.

Farming under Present Conditions.—Mr. O. Blucher read the following paper:—''Producers will agree that farming under present conditions is not a very profitable proposition with wheat at about 2s. 6d. to 2s. 9d. per bushel at country sidings and oats about 1s. 6d. per bushel—the two principal grains grown in the mallee country. Wheat and oats have dropped approximately 50 per cent. in price in the last two years, while the cost of production is practically the same as previously. As supply and demand generally rule the selling price of most produce, we have practically no control over the price, especially as most of our wheat is shipped to other countries. Can we continue to grow wheat at present prices? I am of the opinion that there is nothing else to do but to try and cut expenses where possible and pay more attention to mixed farming. Cheap as butter is, it probably is the best sideline where there are enough hands on the farm to do the work without employing extra labor. A few fowls will assist to reduce bill for groceries, &c., and a few pigs will help to supply meat for household use. Where fences are satisfactory and water available sheep will probably appeal to most, although wool and lambs are very low in price. Sheep give an indirect return because they help to clean the fallow and improve the soil, but generally speaking most farmers in the mallee will give wheatgrowing first consideration. Estimate of costs of production and returns in new mallee country: An average of 9bush. per acre at 3s. 1d. Port Adelaide would be £1 7s. 9d. per acre; expenses on 100 mile radius—freight 5d. per bushel 3s. 9d., bags 2s. 6d., super 4s., 10s. 3d. per acre, leaving a balance of 17s. 6d. per acre to cover the cost of putting in the crop, harvesting, carting of wheat, and wear and tear. This is not a very promising outlook. The general trend seems to be to increase the acreage under crop to make up for the low price. I agree that we should endeavor to grow more wheat, but not by sowing a larger acreage, but rather increase the yields per acre by better farming. In this district it is quite possible to increase the present average yield by at least from 3bush. to 5bush. per acre, which would considerably reduce the cost of production. A few hints as to how this can be done: Do not neglect the fallow. Do not get ready for seeding when the season breaks, but be ready. Do not be seeding when you ought to be fallowing. Do not lose heart, grow the maximum amount of wheat. The price of wheat must improve—be there and benefit when it does.'' (Secretary, P. Crowhurst.)

Alawoona Field Day.—A fine crop of Guyra oats on the property of Mr. H. J. Koch.

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

July 16th.—Present: 23 members.

The Rabbit Pest.—The following paper was read by Mr. E. Thomas:—''It can be said that the rabbit is the worst pest the landholder has to combat, and if left undisturbed will soon take possession of the land and ruin those who depend upon its produce. The destruction of the warrens by digging them out is the best and most effective method of control, and although this will take a considerable amount of time, it will be cheapest in the long run. When digging out rabbits it is advisable to have a couple of good dogs to assist; not only will they save a lot of time in directing to where the rabbits are, but will also hunt for those that are out of the warren. Where the land is rough this is not always possible. In creeks and stony ridges I prefer the use of traps. The success of this method depends largely upon the co-operation of the neighboring landholders, otherwise a large number of rabbits will migrate to the adjoining holdings and very shortly after the trapping has been completed will again return to their old homes. See that the traps are in good order, that the jaws fit together evenly and that they set off easily. Set the trap in a level position and cover it with a thin layer of sand well pressed down around the spring and the outsides of the jaws. If no damp sand is available a piece of paper with a hole cut in the centre should first be placed over the trap and then covered with sand. Always attend to the traps twice a day and close in the warrens; this can best be done with a rabbiter's hoe. The best time to trap is during the early months of the year, because when there are no more rabbits about the job can be done more quickly and more effectively. There are various methods of fumigating practised, which is a much quicker way than trapping, but where the ground is of a porous nature it is not very effective. Where the rabbits are very numerous the laying of poison in the early part of the year is a very quick method of destroying a large number of them, but unfortunately this often helps to spread the blow-fly pest. However, I consider the first two methods mentioned to be the best, and if fowls are kept on the holding the carcasses can be put to good use if boiled for them.'' (Secretary, C. Altmann.)

NETHERTON.

August 10th.—Present: Six members.

Care and Handling of Horses.—Mr. J. Johncock read the following paper:—"It is not my intention to deal with the breaking in of young horses other than to say that in all cases where possible kindness and care should be practised, and also that young horses should not be rushed into harness until they yield to mastering and become docile. Still there are so many good methods that not one of them can be claimed as better than another. To get the maximum of work from the horse careful stabling is necessary. I prefer the practice of each horse in a manger about 5ft. 6in. wide. By so doing one is sure that each horse has its fair quantity of feed. Horses should have plenty of

● FULL MOON.

water and as often as necessary when working. Groom carefully, taking care that the shoulders and all parts that come into friction with the harness are thoroughly cleaned and thus avoid so far as possible sore shoulders and chafing. When attaching the team to the implement always hook up the main draw-bar as short as possible, allowing, of course, free room for turning. The main draw-bar should be raised on skids to a height of 10in. from the ground, because if the bar rests on the ground the weight of the swingle-trees brings too much weight on the point of the shoulders and causes sores. The raised bar throws the weight more to the centre of the shoulders. When making the main draw-bar, allow 1ft. 3in. for each horse. For an 8-horse team, the bar would be 10ft. from eye-bolt to eye-bolt. A 5ft. swing each end for each four horses with 2ft. 6in. swings for two horses, each single horse swing 2ft. 10in. All single swings will then overlap about 4in. Connect all swings as short as possible consistently with free working room. Shorten all chains, just leaving clear walking room. The closer the team is connected to the implement the greater the working power. Be careful that the head couplings closely approximate to the width of the swings behind. The width from centre to centre of the noses of the off and near siders should be the same distance as from centre to centre of the off and near side swings. If the animals are coupled too short they are likely to chafe, if too wide they are working against each other and so losing power. I favor double reins on large teams because the length of reins necessary is too heavy on the mouth of one horse and is liable to make a sore mouth, which makes the horse guide badly, or, as is often the case, making it become slow. When starting to work with a team of fresh horses at the commencement of the season, if the horses rush their work, work them for a short time and then stop for a spell. Do this repeatedly if necessary. Horses usually only rush their work through excitement and this practice will in a day or two wear off and they will then settle down to steady work.'' (Secretary, C. Wilkin, Yumali.)

OVERLAND CORNER (Average annual rainfall, 10.50in.).
August 10th.—Present: 12 members.

Rabbit Destruction.—Mr. C. Smith contributed the following paper:—''The best ways and means of destroying rabbits are decided by the conditions and the time of the year. Phosphorised pollard is the best agent of destruction at the time when rabbits are digging in the ground for feed. By using a poison cart to lay the poison, a much larger area can be gone over. With the machine, the baits can be laid from 1ft. to 4ft. apart, according to the number of rabbits. The thicker sowing often saves going over the ground twice. By the addition of apricot jam to the mixture—2lbs. of jam to 2lbs. of poison—I have found that rabbits will take the baits at almost any time of the year and under any conditions. Two pounds apricot jam, 2lbs. S.A.P., 4galls. pollard, 2galls. bran mixed to right consistency with water will do about 20 miles, with a bait every 3ft., and every bait taken will kill a rabbit. By systematic trapping, one can keep their property fairly free from rabbits, providing neighbors do likewise. In every means of rabbit destruction, the main factor is concerted action by all adjacent landholders. Traps, like all other implements, require a fair amount of experience to make them 100 per cent. efficient. With practical experience and a certain amount of observation, one can very soon pick the faulty traps—loose jaws, stiff jaws, high plates, long catches—all lose their quota of rabbits. A trap in perfect order requires jaws that jam or lock, a level plate, a short catch, a fairly strong spring, and a stout peg. In setting a trap, one must be able to set in dry sand without paper. Wherever possible, set the trap crossways in the burrow, squat, and pad; a rabbit seems to poke his legs through the jaws with this manner of setting. To get the best results one must concentrate on the job; traps should be looked at at least four times a day. When rabbits are no longer coming in or out of a burrow, the burrow should be dug in, preferably with a crowbar; this can be done to a depth of 2ft. After this the burrows should be cultivated down where possible, and by attaching a team to a cultivator or a plough at a distance of 15ft. to 20ft., the horses have very little need to go over the ground where the burrows have been.'' (Secretary, H. Loffler.)

FIELD DAYS, PINNAROO LINE AGRICULTURAL BUREAUX.

GERANIUM, OCTOBER 26th.

Officers of the Department of Agriculture have long emphasised the value of field days as one of the best methods of making contact with primary producers and of keeping them in touch with the latest developments in agricultural practices. This year an increased number of branches of the Agricultural Bureau have included a fixture of this character in their programme of meetings for the year. Messrs. H. B. Barlow (Chief Dairy Instructor), R. C. Scott (Superintendent of Experimental Works), and F. C. Richards (Assistant Secretary of the Advisory Board of Agriculture), attended on behalf of the Department of Agriculture.

Twenty-four members of the local Branch of the Agricultural Bureau met at the institute to take part in a tour of inspection of the farms in the district. The first property inspected was that of Mr. R. Lang, a returned soldier, who is working a block of 860 acres. He has 420 acres under crop this year, 250 acres of which are on fallowed land with Gallipoli, Nugget, and Currawa wheats. The crops on the flat portions of the property are looking exceptionally well, but those on the sand are showing the effects of the excessive wet weather. From a tank situated on a sandy rise water is laid on to the 11 paddocks, into which the property is subdivided, as well as to the house and garden. A fine avenue of sugar gums adds very considerably to the attractive appearance of Mr. Lang's block.

''Two years ago,'' said Mr. Lang, ''I sank a well to augment my water supply. Imagine my surprise when the well had reached a depth of 176ft. to find in the earth brought to the surface the fossilised remains of a shark. The teeth, which I saw, were in a perfect state of preservation.''

Perhaps the best crop inspected during the day was one of 60 acres of Gallipoli sown during the first week in June with 60lb. of graded, dry pickled seed and 1cwt. of super. With a satisfactory finish to the season Mr. R. McDowell, who is a returned soldier, expects it to yield 10 bags to the acre.

Geranium Agricultural Bureau Field Day.—Messrs. H. B. Barlow and R. C. Scott (Department of Agriculture) discuss Pastures on Mr. D. Lithgow's Farm.

VALUE OF SIDE-LINES ON FARM.

Prior to coming to Geranium in 1912, Mr. D. L. Lithgow was farming at Redhill with his father. His property consists of 1,400 acres, all of which is now cleared and permanently sheep-proof fenced. His cropping this year includes 340 acres of Gallipoli, Ranee, Rajah, and Sepoy wheats. One particularly good paddock is showing an excellent growth of clovers and self-sown oats, and for some months past has carried 70 sheep, 13 horses and three foals, and seven dairy cattle. Of four of the latter Mr. Barlow said, ''It is a pity that we do not see more like them on farms in the mallee.'' These are each giving 4galls. of milk a day and producing 60lbs. of butter a fortnight.

Mrs. Lithgow, who came out to her husband two years after the armistice, is keenly interested in side lines on the farm. ''These,'' she said, ''are keeping the house going without us having to draw on our capital. I have 150 White Leghorn hens (Parafield stock), 150 chicks, and 50 Black Orpingtons. At the present time I am gathering 80 dozen eggs a week.

The outstanding feature of the conversation with all farmers interviewed was their firm conviction that ultimately farms in the mallee would be developed as livestock raising propositions in preference to devoting so much attention to cereals.

LAMEROO, OCTOBER 27th.

On October 27th, the Lameroo Branch of the Agricultural Bureau held its first field day, and despite the cold and showery weather there was an attendance of more than 50 members. With the 48 points of rain recorded last week and the 25 which have fallen during the past 48 hours, this year's harvest is assured. Take-all is noticeable in some crops, but Mr. R C. Scott does not expect it to affect the yields appreciably. In common with the whole of the State, Lameroo is having a great year for feed, and livestock are in wonderful condition. The fallows are inclined to be dirty, but this can be attributed to the continual cool and showery weather making it almost impossible to cope with weeds. Mr. H. Schultz, whose property was the first inspected, came to Lameroo from Point Pass with his brother seven years ago. An exceptionally fine crop of 99 acres of Gallipoli wheat, sown with 1bush. of seed and 90lbs. of superphosphate, is expected to yield eight bags to the acre.

From a paddock of 130 acres of Rajah wheat, free from weeds and disease, Mr. C. Hentschke expects a yield of from eight to 10 bags to the acre. A crop of New Zealand oats, a variety new to the district, should give a good cut of hay. All told, 530 acres are under crop. Mr. Hentschke has a three-year-old Clydesdale colt bred by Mr. Kelly, of Riverton.

Lameroo Agricultural Bureau Field Day.—The Progeny of two Clydesdale Mares mated with a Percheron Horse, the Property of Mr. W. J. Morcomb.

"Although I have a tractor," he said, "I only use it at seeding time. With prices for wheat so low, the tractor takes too much money out of one's pocket."

The farm carries 10 milking cows, with a pure-bred Jersey bull as the head of the herd.

"My 20 years' experience of mallee farming," said Mr. Hentschke, "have convinced me that much of the success of growing wheat in these areas is wrapped up in early sowing. Seeding must be completed by the end of June. July sowing is a gamble. The observance of this practice, and the keeping of an adequate flock of sheep, say, 400 on a 1,100 acre farm, will go a long way towards the growing of good crops."

Messrs. Spratt Brothers work two properties, in addition to having an interest in another farm. They are regarded as some of the best farmers in the district. From a tobacco tin of Derf wheat brought out from Germany Mr. Spratt has this year grown an excellent crop.

BARLEY PAYS BETTER THAN WHEAT.

"My favorite varieties are Felix and Sultan," he said, "and my bothers and I make a regular practice of getting fresh seed from Roseworthy College every three years. Since we came here from Wasleys in 1926 we have averaged 17bush. to the acre. We do all the farm work with horses and would not think of using a tractor. We also devote more attention to barley than most farmers in this district and have 90 acres under this cereal. Our barley crops in the past two years have been more profitable to us than wheat. This year the best of it will go 10 bags to the acre."

Messrs. Needs Bros. were among the first settlers to come to Lameroo, their block of 1,500 acres having been taken up by their father in 1907. The cropping includes 750 acres of Gallipoli, Ranee, and Nabawa wheats, and 50 acres of oats. The farm carries

350 ewes, and 350 White Leghorn and Black Orpington fowls, new blood being introduced from the Parafield poultry farm and the Goodheart plant at Murray Bridge.

When the party called at Mr. E. J. Trowbridge's farm his son had just started cutting a crop of Ranee wheat, sown for hay on stubble land. Three hundred acres will be reaped for grain, and Mr. Trowbridge expects the crops on the flats to go seven bags to the acre, but on the sandhills the returns will be a good deal lighter.

Mr .J. Kernick works a farm of 450 acres. He has 190 acres under wheat, his best crop being one of Ranee, which should give an average of 10 bags to the acre.

Mr. W. J. Morcom has long been interested in the improvement of the horses of the mallee, and is one of the committee responsible for the foundation of the Lameroo Horse Breeding Society. Members of the party were keenly interested in a group of eight Percheron-Clydesdale horses, the progeny of two Clydesdale mares.

Perhaps there is no more familiar name than that of Koch in the Lameroo district, and Mr. John Koch, who resides at Walkerville, was one of the pioneers of the mallee. The properties of three of his sons in the persons of Messrs. J. L., C. E., and A. J. A. Koch were the last visited. Mr. J. L. Koch has charge of the Clydesdale colt, by Bold Alexander from Lady Fabric, recently purchased by the local horse breeding society. As a sideline he is concentrating on poultry, having 150 White Leghorn hens of Parafield strain and 600 chickens. Mr. A. J. A. Koch is a past president of the Lameroo Branch and a life member of the Agricultural Bureau. Like his brother he is devoting a good deal of attention to poultry, and has 150 White Leghorn hens and 300 chicks. His Indian runner ducks, kept under ideal conditions with a concrete swimming pool, and 50 half-bred large white Berkshire pigs were very favorably commented upon. He has a nice crop of Ranee wheat and five acres of Wimmera rye grass which he proposes to harvest for seed.

Lameroo Agricultural Bureau Field Day.—A Fine Crop of Oats on the Farm of Mr. H. G. Schutz.

Referring to the day's tour, Mr. Scott said that the prospects of the wheat harvest pointed to better returns than those of last year. Only one poor crop was inspected throughout the day. With the cool weather that has been experienced crops are maturing most satisfactorily.

Other properties inspected were those of Messrs. G. H. Twelftree, J. H. Jericho, and G. Morris.

PARRAKIE, OCTOBER 28th.

''Although take-all, excessive wet weather, and rabbits have levied their toll on the crops, nevertheless there will be a lot of wheat harvested this year in the Parrakie district,'' said Mr. D. Sanderson (chairman of the Parrakie Branch of the Agricultural Bureau), when speaking at the field day held under the auspices of the local Branch of the Agricultural Bureau on October 28th. ''We realise that during the past three years we farmers at this end of the line have had a better time than those further east, and we do not begrudge them the fact that fortune has smiled more favorably on them this year.''

The attendance was somewhat disappointing, but all members said that the day had been most instuctive, the talk given by Mr. Barlow during the lunch hour on various aspects of the management and breeding of dairy cattle being singled out for special mention.

Mr. O. Hienzel's property of 954 acres was first inspected. Two hundred acres of Currawa, Walker's Wonder, and Gallipoli wheat and 36 acres of oats are under crop.

Mr. S. H. Nicholls, who before coming to Parrakie was share farming for five years with Mr. A. S. Hawker, of Rochester, is working a returned soldier's block of 870 acres. A nice crop of 77 acres of Gallipoli will be entered in the Chandos crop competition. A crop of 33 acres of Gluyas is showing signs of "going down." Fortunately Mr. Nicholls has a header and hopes to be able to harvest it without any serious loss.

Mr. Peter Ross, when he was farming at Mallala, was looked upon as one of the best agriculturists in that district, and since coming to Parrakie, where he took up an abandoned block of 1,000 acres, his right hand has not lost its cunning. Last year, with a magnificent crop of Gallipoli which yielded 36bush. to the acre, Mr. Ross brought the first prize in the Chandos crop competition to Parrakie. This year he is again pinning his faith to this variety, and has 400 acres of it in crop. He realises that livestock operations are destined to play an important part in the future development of the mallee, and with this end in view is sparing no effort in improving the standard of his horses, cattle, and sheep. As evidence of this he recently purchased a two-year-old registered Clydesdale stallion, which won first prize at the Lameroo show. As head of his herd of cattle he has an exceptionally well-grown yearling Shorthorn bull. His 150 breeding ewes have 150 lambs from three fine Dorset Horn rams bred by Mr. Coleman, of Balhannah.

Parrakie Agricultural Bureau Field Day.—A Crop of Gallipoli Wheat on Mr. P. Ross's Farm.

To ensure adequate fodder supplies, Mr. E. Isaacson has sown 60 acres of fallow with Lachlan and Algerian oats, using 1bush. of seed and 90lbs. of super. These crops presented a fine sight, and a cut of 35cwt. to two tons is expected from them.

Pioneer of the District.

Mr. A. J. Beelitz, a pioneer of the district, took up his holding of 3,600 acres 25 years ago, and has truly carved out a home from the scrub. There are 950 acres in crop for the coming harvest, and in some of the paddocks members saw very striking examples of the damage rabbits are doing. An area of 800 acres of fallow has been ploughed for next year. The property carries 700 sheep, including ewes and lambs, the latter from Southdown rams.

"My herd of 10 dairy cows is giving 9galls. of cream a week, and also supplies the local refreshment rooms with milk and butter," said Mr. Beelitz. He is a member of the Red Comb Egg Association, through which medium he markets the produce of his 200 White Leghorn and Black Orpington hens. Two hundred day-old chicks were purchased this year to maintain the strength of the flocks. Perhaps the most attractive improvement on this property is the four acres devoted to vines, fruit trees, and vegetables.

"This," Mr. Beelitz said, "has proved a very payable sideline to my farming operations. I am able to supply practically all the requirements of the district, and in addition dispose of a fair quantity at the sales that are held periodically."

Although the garden has been watered continuously for 15 years with bore water, at the time of inspection the trees were loaded with fruit, and cabbages, beet, lettuce, onions, &c., were growing in profusion.

After having spent the greater part of the week among farmers at Geranium, Lameroo, and Parrakie, Mr. Barlow said that so far as dairy cattle were concerned it was more than pleasing to be able to report that there was a genuine desire on the part of settlers to improve the quality of the cows. As evidence of this he had been asked to make inquiries on behalf of farmers for the purchase of pure-bred Jersey and Shorthorn bulls.

SOUTH AND HILLS DISTRICT

CURRENCY CREEK.

June 20th.—Present: Nine members.

Beekeeping.—Mr. L. Collett read the following paper:—"Kinds of bees found in the hive: The queen bee is the mother and director of the hive. She is longer than the ordinary worker, and her work is laying the eggs for the next generation of bees. Each egg is laid in a separate cell—drones, workers, and queens' cells. The drone cells are larger, longer, and rounder than the worker cells. The worker cells are hexagonal, and can be quickly converted into honey cells when breeding and rearing is done for the season. The queen cells are long (about 1½in.) and are placed on the side of other comb. The drone is the male, and a hive is usually stocked with about 30 drones up to a couple of weeks after the young bees are hatched. Then they are killed off by the workers. They are stingless, and are honey eaters after their work is done. The worker: About 40,000 workers are contained in what is usually called a good swarm, requiring a double hive in which to work. The worker goes out with the first rays of sunlight and will go up to five miles from home to obtain honey. It is sexless. The usual methods of getting honey on a farm are—*Tree honey* is obtained by cutting open the bees' supply in the tree and taking out the comb, after driving back the bees with smoke. The comb is washed, and the honey is strained through a cloth. *Box honey.*—The bees first of all must be driven back from the comb with smoke. Then the comb taken out by cutting it away from the roof, and thus spoiling all the comb for further use. *The patent hive* is the most economical method of keeping bees. The lid of the hive lifts off and the frames are taken out, the bees being brushed off with a soft-haired brush. A hot knife is run across the comb, cutting or melting off the caps of the cells. The frames are placed in the extractor and whirled around, the centrifugal force throwing the honey on to the sides of the extractor. The comb remains on the frame to be filled and sealed again by the bees. It is ready for retaking in a good season in about nine days. *Pests in the bees.*—The moth takes a very severe toll on bees. It is usually in the form of a caterpillar that spins a web over the comb and in the corners of the hive. If a box gets the moth into it the best way is to move the bees to another box and boil the infected one. Ants are a nuisance among bees, and frequently kill out a swarm almost as quickly as moths. *Bird pests.*—Bee-eaters or native starlings, magpies, and various other insect eaters.'' (Secretary, D. Gordon.)

August 15th.

The Truck on the Farm.—Mr. H. Higgins read the following paper:—''In spite of the universal cry of 'back to the horse' that is being heard throughout the country at the present time the motor truck has come to stay. There are possibly many farmers who would have been well advised to have refrained from purchasing a car, and who now would find the money invested in it of great value in this time of depression, but the truck meets as many demands, and is capable of handling the produce of the farm so cheaply and well, that the farm where the truck could be deemed unnecessary would be hard to find. Moreover, the modern truck can have its claim fitted up so comfortably that the owner should have no compunction in using it for social purposes when these arise; but in no case can the use of a car be reversed to carry produce without serious damage to its body work. Therefore one would stress the importance of looking after and maintaining the truck so that it may give the utmost of service and show the smallest amount of depreciation. The tyres on a new truck appear to need little attention, but very often a new valve will leak slightly until it takes its seating; and the cover, being new and stiff, will appear to contain more air pressure than it really does, and thus the importance of having a reliable pressure gauge in one's kit, for no one, however clever, can ascertain by looking at a cover the correct pressure it contains, and it is of vital importance to the walls of the tyre that it has sufficient pressure to prevent the fabric from being cut or broken when passing over a hard obstacle. A trip with a load on a partly deflated cover may not show any evil effects for perhaps months after the journey has been taken, but should the driver have been unfortunate enough to break some of the cords which go to make up the fabric of the cover, he will in the end certainly get a puncture caused by the tube being bitten in its movement in and out of the crack when the truck is in motion. This puncture will really be a blessing in disguise, for on taking out the tube the break in the wall will be evident, and can then be strengthened—either with a liner or plaster—thereby saving what would certainly end in a burst, with the probable destruction of both cover and tube. Watch the covers and test the pressures, especially before carting heavy loads, and also have the best covers on the driving wheels. *The Battery.*—Nearly all present models have coil ignition, and this part of the truck is its 'heart.' Be sure to have the battery firmly and tightly fixed in its cradle, for a loose fixture will more readily spill the acid, besides seriously injuring the plates to which the poles are attached. This acid is very harmful to clothing and metal work, and will soon eat through the iron box or cradle which holds the battery in place Cover the plates with pure water—and no more. Check over once in a while the nuts making contact to various electrical parts of the truck, and do not allow any sulphating to accumulate around the poles—this will eventually act as a non-conductor and prevent the current from flowing through. *The Generator.*—This hard-worked little unit is running at high speed continuously, and as it is free from trouble, one is apt to forget its existence. Once a year the plate cover should be removed, the brushes cleaned, and, if necessary, the commutator brightened up with '00' sandpaper. There are also two bearings which need a few drops of oil every 1,000 miles. Watch the ampmeter, and should it fall below 6 to 8 amps in day time inspect the fan-belt for looseness, or it may be necessary to advance—anti-clockwise—the third brush. The distributor should be inspected occasionally, and the points kept clean, also the greaser just below it should have a few turns every 200 miles, for which this bearing—which the greaser functions—becomes worn most irregular firing will result, and eventually stop the motor. The coil should also be firmly screwed down to the frame or plate, and any rust around the connections be removed (rust being a non-conductor). Usually a renewal of oil every 1,000 miles will render good service, but the ersults of using oil for too many miles—or of second quality—will not show any injurious results immediately. One could probably use some of the high grade oils 2,000 or even 3,000 miles, and the engine would still appear to function satisfactorily; it is only after some time has elapsed of this treatment that one can detect a falling off of power, and an increase of noise in the engine. On dismantling it will probably be found that the pistons require over-sized rings, and the cylinders are more oval than one would expect. It is a very expensive practice to economise in oil. I suggest making a suitable pit where one can stand upright and check over the brake connections, springs, steering gear, body bolts, etc. In this way one can go over the important parts of the chassis in a short time and in comfort. Make this a regular practice—say every 1,000 miles, when the oil is renewed, and for this purpose see that the truck has a reliable speedometer. Keep check of each time of inspection by noting the mileage on the speedometer. Have a system—work over the truck regularly and you will be saved a great deal of expense and delay when you can least afford it.'' (Secretary, D. Gordon.)

FRAYVILLE.

July 12th.—Present: Eight members.

Farm Machinery.—The following paper was contributed by Mr. T. Eichler:—''With the high price of farm machinery at the present time, it is not only necessary to buy an implement most suitable for the work required, but also to give it every care and attention. Three of the most important points are adjustment, lubrication, and protection. If these points are neglected there will be rapid depreciation, breakages, and the loss of valuable time. For harvesters, binders, and combines, when not in use, good shelter is most important. This means a good shed so that fowls cannot roost on any implements. The harvester is a machine which has more wear and tear than any other, therefore it is necessary to use plenty of oil. Before starting reaping, the machine should have a good overhauling, all oil holes cleaned out to see that they are free from dirt. Pour a little kerosene through the oil holes to ensure that each part receives a supply of oil. Care should be taken when movable bearings are altered that they are not adjusted too tightly. The binder needs similar care to the harvester. The main point is to remove the canvasses after hay cutting is finished and hang them in a mouse-proof shed. The combine should be cleaned out as soon as seeding is finished, take out the stars and soak them in water for a day, then clean them off with some rough material. Also pour kerosene through the wheat feed if dry-pickle has been used. The plough and cultivator do not require much attention except the usual oiling.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SUMMER, 1933.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—10s. per Setting of 15 Eggs; Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—15s. per dozen; £5 per 100.

BLACK MINORCAS.

EGGS.—10s. per Setting of 15 Eggs; Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—15s. per dozen; £5 per 100.

Free on Rail, Salisbury. **DELIVERY.—CHICKS—February and Early March.**
EGGS—January and February.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Victoria Square, Adelaide.

C. F. ANDERSON, Poultry Expert.

Harrows should be sharpened occasionally, so that they stir up the ground and kill any weeds on the fallow. If the farmer has a small blacksmith shop he can do most of the repairing himself and thereby save expense.'' (Secretary, V. Eichler.)

HARTLEY (Average annual rainfall, 15 to 16 in.).

June 15th.—Present: 12 members.

Hints for the Farm Carpenter.—Mr. W. Yeates presented the following paper:—''All farms have a few carpenter's tools, and in the care of these is the difference between whether the job is a pleasure or hard work. A few chisels are among the most necessary tools. These should always be ground square across and with a good bevel. Care should be taken when grinding to have the bevel a shade hollow if possible, never on the round. An ordinary firmer chisel is satisfactory for soft wood, but for hard woods such as red or blue gum, jarrah etc., a good strong socket chisel is best. For the harder woods, do not grind the chisels too thin. After grinding any cutting tool, be sure and finish it off on an oil stone. This gives it a better cutting edge and keeps the tool from rusting. The handles of chisels also need care. Never use a hammer on them. A wooden mallet is easy to make. A plane or two will be very useful. These also should be well ground back. Keep one of the planes for rough work. A wooden plane is best for this and instead of grinding it straight across, have it round—almost in a half-circle, for the finer work. Keep the edge of the other plane almost straight across. A little raw linseed oil rubbed into the plane keeps the wood in good order and helps to make it work better. The hand saw is an almost indispensable tool. For cutting across the grain, seven teeth to the inch is a handy size. The setting of a saw is as important as the sharpening. It should have enough set to clear itself easily. In doing this, care must be taken to keep all the teeth even. If one is set a litte too much, it causes the saw to drag. For ripping—cutting with the grain—a saw with four teeth to the inch can be used, sharpened so that they point well forward. Too much set on this saw is worse than not enough because it makes it far harder work and much slower. In damp weather be sure and wipe the saw dry before putting it away and rub it over with an oily rag. Timber is expensive and one naturally is anxious to save as much as possible without losing any of the strength; therefore, for joist rafters or beams the timber is wanted more in depth than width; a 4½in. x 1½in. is better than a 4in. x 2in., and less timber measurement; likewise a 6in. x 2in. on its edge is stronger than a 5in. x 3in., and a saving of about one-fifth of the timber.''

Cows.—Paper by Mr. J. Brook:—If it were not for cows many farms would not be operating. It is only the ready money that is keeping cows going. So far as profits are concerned, a cow-keeper—if he had to pay for labor and feed—would be out of pocket. When selecting a cow care should be taken to see that she is an upstanding animal, with four sound quarters, a good escutcheon, and young. The bull need not be a pedigreed animal, but he should be masculine in appearance and of good conformation. For this district I prefer the Shorthorn or Friesian; they will stand the cold better than most other breeds, and give more milk. Next select a calf from this cow that nearest resembles the breed. It may take two or three calves to do this. Bring the calf into profit when she is two years old to give it a good start before it has the strain of being milked. A calf coming in too young may have a good deal of trouble, and even be lost before many years of milking. The calf should run with the cow until the milk is fit for human consumption. Take the calf away, tie it up in a place where the cow cannot see it. The following method of feeding a calf is recommended:—Feed the calf the first milking after it is taken away by allowing it to suck a piece of hollow rubber about ½in. thick, at the same time gradually raising the bucket of milk (say ½gall.) until the calf starts to suck it up. By doing this twice, most calves will drink without any further trouble. Market bull calves, except a special one that will make a good sire. Keep the best heifers. To raise a herd of 20 cows will take from the bought cow, providing the best calf is not very uncommon, about 12 years. After that there will be the sale of the bought cow and other calves. One calf should be kept each year after the herd is made up and one cow sold, so that the herd is kept young. Do not use the same bull for more than three years. All cows, bulls, and calves, 18 months old or over, should be dehorned. Feed the cows with chaff at least once a day all the year round. It helps to harden them in winter and keeps condition on them in summer. A cow must not be left in one pasture too long for two reasons:—(1) The grass gets too short, and a cow does best on long grass. (2) If eaten right down every year, in about four years there will be no grass, because all the seeds are eaten and none left to germinate. *Water.*—Keep plenty of fresh drinking water in the cow yard. If possible keep the cows in a paddock in which there is a creek, they will then be able to drink at will. The main part of milk is water; that is why they drink so much. Milk as regularly as possible, about every 12 hours. Any young person setting out to start a dairy should seek advice regarding the most suitable cow for this district. Also, keep the biggest cow or calf that can be procured—size is best when the cow is finished with and is marketed, and they are best also for breeding. Keep the cow-yard and all appliances used in the dairy as clean as possible. (Secretary, D. Harvey.)

CROWN LANDS.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

R. S. RICHARDS, Commissioner of Crown Lands.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

Branches of the Agricultural Bureau have been advised that District Conferences will be held as follows:—

River Murray Swamp Areas.—At Murray Bridge, Thursday, February 16th (Secretary, Mr. Max Hoare).

Dairying—At Mount Barker, Thursday, May 11th (Secretary, Mr. P. Wise).

Each Conference will be opened at 10.30 a.m.

Farmers' Relief and Debt Adjustment.

In a recent announcement to the Press the Premier (Hon. L. L. Hill) stated that the Bill which the South Australian Parliament passed last session for the re-enactment for another year of the Farmers' Relief Act was a continuation of the policy of the Government to assist the primary producer by every economically sound and reasonable method available.

A committee has been appointed to investigate the whole question of the further policy of assistance to necessitous farmers and debt adjustment, and continuation of present legislation for another twelve months will allow ample time for this investigation to be carried out. This committee is comprised of representatives of the Government, the farmers, Chambers of Commerce and Manufactures, Stockowners' Association, and associated banks. The scope of the inquiry will be limited to South Australia, and the committee is required to present its report by February 14th, 1933.

Certain amendments have been made to the laws under which the Bank is financing this year's agricultural operations, and under which the proceeds of this year's crops will be distributed. These amendments have been included as the result of experience of the first year's operation of the Act which put the Bank in a position to suggest a number of improvements in the details of the scheme. It is intended that they should operate next year in respect to this year's crop, and in 1934 in respect to the 1933-4 crop. The substance of these amendments is:—

That farmers will be able to retain out of their crops a reasonable amount of grain for grist.

That farmers, upon delivery of their crop in accordance with the Act, are required to forward to the Bank the cartnotes or other documents issued by merchants or the Pool as evidences of delivery.

Where an applicant for relief retains part of his crop with the approval of the Bank for seed, fodder or grist, and the Bank is satisfied that the whole or part of the amount retained is not being used for the purpose for which it was intended, it may direct the applicant to sell or pool the balance.

Merchants, and the pool, will be required to pay the Bank for wheat delivered in its name by farmers even though the Bank is not in a position to produce any documents and the Bill indemnifies the merchants and the pool against the consequences of their having paid the money to the Bank in these circumstances. The Bank will be enabled to pay, with the proceeds of the assigned crop, as a fourth preference, interest on advances made to farmers by the Crown which, although not secured by a mortgage, are by law a first charge on the applicant's land. The principal item which will come under this provision is interest on advances for fences and water piping. Provision is made for payments to mortgagees in cases where the mortgage on a farm does not purport to provide for the payment of interest. Such mortgagees will be enabled to rank for a dividend equal to interest for one year at 5½ per cent. on such of the moneys

N.T.1

secured by the mortgage which the Bank considers to be the amount of principal outstanding. Provision is made also for payment of one year's interest on an amount representing the capital value of any moneys secured by an encumbrance over the farm.

Where a farm is held under an agreement to purchase which does not purport to provide for the payment of interest on the purchase money the vendor of the farm shall be entitled to rank for payment of interest for one year at 5½ per cent. on the outstanding purchase money.

Payments of interest on Bills of Sale covering farm machinery will be limited to cases where the machinery was necessarily used in the production, harvesting, or marketing, of the crop.

If on or after October 1st the Bank has in hand any undistributed balances of the proceeds of the sale of any crops which are insufficient to pay 1s. in the pound on any outstanding claims, the Bank can postpone the distribution of those amounts and treat them as proceeds of the subsequent crop.

Several further concessions are made to applicants for relief in the clauses which provide for financing farmers for 1933-34. The scheme proposed is generally similar to that in operation in connection with the present season's crop, but there are minor points of difference, mainly as follows:—

Applicants may apply for finance to pay fire insurance on farm buildings, and for reasonable sums for medical, dental or nursing expenses, opticians' fees or funeral expenses payable for services rendered to the applicant or any member of his family during the twelve months beginning on March 1st, 1933, for veterinary services, for premiums up to £20 on life assurance policies of the farmer or any member of his family, and for subscriptions to friendly societies.

Any applicant may withdraw his application by a simple process set out in the Bill.

At present any trading bank, merchant or other person who finances or gives credit to a farmer, can obtain a certificate from the Bank for the amounts due and get payment of these amounts out of the proceeds of the crop. The present Bill proposes to limit this section to trading banks and merchants.

Security of tenure will be given to a farmer who is the lessee of his farm similar to the protection given a farmer who holds his farm under agreement to purchase.

In concluding his statement the Premier remarked that the first year of administration of the Act reflected the greatest credit on the Bank and all others concerned in its operation. It was unavoidable that there should have been some cases in which individuals encountered hardships and difficulty, but the amendments to the Act should still further minimise these.

Certified Ryegrass Seed.

The Hawke's Bay Association of Certified Grass Seed Growers has pointed out that farmers who desire to purchase certified ryegrass from Hawke's Bay should look for certain markings on the bags, tags, and insert slips. Merchants in the Hawke's Bay district stencil the bags with "Guaranteed Hawke's Bay grown, machine dressed by (name of firm)." The Department of Agriculture supervises all the certification, and they issue insert slips and tags according to the classification of the seed. On the insert slips and tags there will be found the words, "Grown on Registered Area No. ...." Following this will be "H.B. (grower's No.)," such as H.B./107, and then the paddock letter following the registered No. "H.B." stands for Hawke's Bay District, whereas if "S.C." is shown on the tag it would indicate that the area harvested is in South Canterbury. There is nothing to show the farmer that the seed is grown in Hawke's Bay except by looking for "H.B." on insert slips and tags or, in some cases where firms adopt the method of branding the bags as follows:—"2 H.B./107," and paddock letter over the code letter for seed classification.

VETERINARY INQUIRIES.

[*Replies supplied by Veterinary Officers of the Stock and Brands Department.*]

"Cleve" reports cows difficult to get in calf. Animals show decided inflammation of the vagina.

Reply—1. The condition is probably vaginitis. Try the following treatment:—(1) Douche out three times weekly with warm Condy's solution (port wine color); (2) stop a week before cow is due to come on heat; (3) one hour before service douche out with warm bicarbonate of soda solution (dessertspoonful to a pint). Just prior to doing this, rake out the outer passage of the cow. 2. You may be giving the bull too much work, especially in the case of a bull six years old that is kept in a small yard.

Rendelsham Agricultural Bureau reports—(1) *Young pigs with scabs and sores on sides of mouth;* (2) *pigs* 8-10 *weeks old, arched backs and weak in hind quarters;* (3) *young pigs scouring badly;* (4) *a cure for worms in pigs;* (5) *is bluestone beneficial to pigs—if so, what quantities to give.*

Replies—(1) This condition is due to infection through minute wounds in the skin. Bathe affected parts with warm water to which has been added a little lysol and some washing soda. When scabs are thus removed, dry gently and then smear lightly with 5 per cent. carbolised vaseline. Two or three treatments with this should effect cure. The pig should at outset of treatment be moved on to fresh clean quarters and the old quarters thoroughly cleaned up and disinfected. (2) Move pigs into fresh comfortable quarters where they can be exposed to sunlight. Give each a dose of 2 tablespoonfuls of castor oil in a little milk. Give 1-2 teaspoonfuls of cod liver oil per pig daily in swill feed, also ½oz. superphosphate. Include some fresh chopped green feed in the daily ration. (3) Give each pig a dose of 4 tablespoonfuls of castor oil; put on to light diet of easily digested feed of a swill nature in which skim milk forms a large portion. To each feed add ½ pint of limewater per pig. (To make limewater put 2lbs. fresh lime in bucket and fill up with water. Leave for 24 hours, stirring occasionally. Then decant off the clear liquid, leaving the sediment behind.) Pay particular attention to cleanliness of all feeding and drinking utensils and quarters and see that all feed given is of wholesome nature. If the diarrhoea is persistent and severe, 5 drops of chlorodyne per pig can be given daily for two or three days. (4) For three days in succession dose with turpentine at the rate of 1 teaspoonful per 100lb. liveweight. Keep the pigs hungry for a few hours each day and then give the medicine in swill feed. Twenty-four hours after the last dose of turpentine has been given, give a dose of 2ozs. Epsom salts in solution per pig. The pigs will drink this purge if diluted

at the rate of ½oz. salts to each quart of warm milk or slop. To prevent reinfestation, move pigs to fresh clean quarters and thoroughly clean the quarters, feed troughs, and drinking vessels out regularly, at least once a week. (5) Bluestone is not commonly used for pigs, but there is no reason why it could not be given to them with quite satisfactory results as a vermifuge (worm killer) and tonic. It has given quite good results when used for this purpose with other stock (especially horses and sheep). It would, however, be necessary for the pigs to be treated individually and the prescribed dose accurately measured for each animal. If the pigs were just dosed with it in a mob from a common feed trough, some of the animals may get more of it than others, and it would be likely to produce severe digestive disturbances in them. The dose would be 5 grains per pig (up to 10 grains for large pig) twice daily for 5 to 7 days, followed up 24 hours after the last dose by a purge of Epsom salts or castor oil. The bluestone could be administered either as a pill, a drench, or well diluted in swill feed.

Narridy Agricultural Bureau reports (1) *three-year-old gelding eating manure and continually lying down;* (2) *cow with large bladderlike lump protruding from vagina.*

Reply—(1) Starve the gelding for 18 hours. At the end of that time give a drench of raw linseed oil, 1½ pints; oil of turpentine, 4 tablespoonfuls. Shake carefully before giving. Subsequently give 1 teaspoonful of powdered nux vomica night and morning for a fortnight. To give, mix with treacle and smear on the tongue. Feed regularly and on good-quality feed. (2) The condition is a prolapse (partial) of the vagina and is usually associated with a fat condition and want of exercise. You can keep the cow, but try and reduce her condition a little.

"Myponga" asks what is mange in cattle.

Reply—True mange in any animal is due to mange mites, which burrow into the upper layers of the skin, causing intense irritation, loss of hair, and thickening of the skin of the invaded area. True mange is contagious. It is uncommon in horses and cattle in this State. However, the term "mange" is usually applied by most farmers to any condition of the skin where there is a loss of hair.

AGRICULTURAL INQUIRIES.

[Replies supplied by Mr. W. J. Spafford, Deputy Director of Agriculture.]

Rust-Resistant Wheats.

Balumbah Agricultural Bureau asks: "What has been the experience of the Department of Agriculture with rust-proof and rust-resistant wheats?"

Reply—Most of the principal wheats grown in South Australia are fairly rust-resistant, or at all events rust-escaping, when grown at the proper season of the year, but nearly every one of them is liable to attack by rust in some peculiar season, and when they are grown out of their proper season. For instance, in the present season, one of the most rust-resistant varieties grown in the country—Early Gluyas—has been very badly affected by rust, but in every case seen it was because this early variety was sown early in a peculiar season. Early wheats sown in April got a good start, and as the weather in May was mild, warm, and spring-like, the plants made strong sappy growth, and headed by the end of August or the beginning of September, and when the muggy weather of the week ending September 17th was experienced the plants had not hardened sufficiently to enable them to withstand the rust. These same varieties sown in May would not have been affected by the disease. There are a number of cases of farmers sowing the same variety on the April rain and during the period mid-May to mid-June, and although the early sown crops have been affected by

YOU can't afford any risk of tractor breakdown during harvesting. That is one reason why you should use Mobiloil. You want to get your harvesting done as quickly as possible—that's another. Still another reason is the need for the greatest economy. Mobiloil will give you that.

Mobiloil is made to stand up to the hardest work, and it will enable your tractor to stand up to it, too.

VACUUM OIL COMPANY
PTY. LTD.

rust in most cases the late sown crops of the same variety are quite rust-free. In such a season as the present there is no avoiding some damage by rust, because it is essential to sow early in the season in some districts, and these wonderfully long-drawn out seasons are so unusual that they cannot be anticipated.

With the type of varieties of wheats being grown at present there is little to fear from rust in ordinary years, but occasionally we experience a season when even the most resistant wheats suffer.

Treating Hay with Sulphur.

Bundaleer Springs Agricultural Bureau asks: "Will the application of sulphur keep mice out of a hay stack?"

Reply—The Department of Agriculture has never treated hay stacks with sulphur to keep down the ravages of mice, but the damage done by this pest is considerably reduced in wheat stacks if a little sulphur is sprinkled on the bags whilst being stacked, and we have often been informed by reliable farmers that success has followed the use of this material in their hay. We certainly consider that the sprinkling of sulphur into hay at the rate of about ¼cwt. per ton of hay is worth trying, but we believe the best way to ensure freedom from mouse attack is to cut the hay on the green side, and to stack it on a platform built on posts on to which an overlapping sheet of tin has been fixed, or on to which a kerosene tin with the bottom cut out has been placed.

Pea Straw as a Stock Food.

Blackheath Agricultural Bureau asks: "Is good clean pea straw of much food value to stock, and would it be likely to prove injurious to cattle and horses if let have free access to it?"

Reply—Dry pea haulms make fairly good feed for farm livestock, provided that they are clean and free from moulds. They never prove injurious to horses or cattle but on the other hand are a first class roughage for animals on sappy pastures or when receiving a lot of concentrated foodstuffs. The following analyses give a comparison of the feeding value of pea straw, wheaten hay, and lucerne hay:—

Feeding Stuff.	Composition.						
	Moisture.	Ash.	Crude Protein.	Fat.	Nitrogen-free Extracts.	Fibre.	Starch Equivalent.
	%	%	%	%	%	%	%
Pea straw	10·0	6·9	9·4	1·6	35·1	37·0	16·9
Wheaten straw.	10·0	5·0	3·1	1·3	37·7	42·9	12·1
Wheat	10·0	6·2	5·1	0·8	53·5	24·4	30·9
Lucerne hay ..	10·0	8·0	14·4	1·7	38·2	27·7	33·3

Take-all.

Frayville Agricultural Bureau asks: "What is the cause of take-all? This disease appeared in a paddock which was ploughed in October, harrowed twice before harvest, cultivated in April, and drilled in May, with combine."

Reply—Take-all is a fungus disease which lives on the roots and base of the stems of wheat plants. It is encouraged by excessive looseness of the soil. It is controlled by:—1. Burning stubbles of affected crops. 2. Growing oats after wheat. 3. Carefully fallowing the land to a very shallow depth. 4. Delaying seeding until as late as is safe for the district. 5. Using more superphosphate than has been the practice. 6. Rolling the land after seeding if it is at all on the loose side.

Wild Oats.

Frayville Agricultural Bureau asks: "What is the best method to get rid of Wild Oats?"

Reply—Wild Oats are very difficult to eradicate, particularly from land that is inclined to crack when dry. Frequent shallow working of the fallow, constant use of sheep, and delaying seeding until the oats have germinated and been killed, is the usual procedure followed where this weed is troublesome.

Grasses for the Clare District.

Stanley Flat Agricultural Bureau asks: ''What grasses are recommended for the Clare district to give early winter growth?''

Reply—There are very few grasses that can be grown for a certainty in the Clare district to produce early winter growth, but good results should follow the establishment of Wimmera Rye Grass and *Phalaris tuberosa.*

Wimmera Rye Grass is easily and cheaply established where cereal crops are grown for grain, by mixing seed with the superphosphate, as it is put in the manure box of the seed drill at the rate of 2lbs. per acre. The harvesting machines pick up the seed and distribute it fairly evenly over the fields. If to be established as pure stands about 10lbs. seed per acre should be drilled in with 1cwt. of superphosphate. If to be mixed with Subterranean Clover about 6lbs. to 8lbs. seed should be added to 4lbs. of the Clover seed, and sown to each acre.

Phalaris tuberosa can be established by transplanting rooted sections about 2ft. apart each way in well cultivated land, or seed can be sown directly into the field. On good soil preparation a seeding of 2lbs. per acre mixed with superphosphate is sufficient, and then when the plants are one year old Subterranean Clover can be sown as well. *Phalaris tuberosa* is a true perennial grass which makes its principal growth during the winter, and as such is rather unique in so far as the cultivated grasses go. It should do well at and near Clare.

Although Wimmera Rye Grass is an annual it seeds itself down with such certainty that it behaves much as a perennial, and so it and *Phalaris tuberosa* can be recommended for permanent pastures.

Weevil in Grain and Sheds.

Langhorne's Creek Agricultural Bureau asks: ''Treatment for weevil in grain —how to rid bins and sheds of both eggs and adults?''

Reply—Buildings and receptacles can be readily freed of weevils if they can be made air-tight by fumigating with Hydrocyanic Acid gas, but very few sheds on farms can be treated with this highly poisonous gas, and the problem is an extremely difficult one in most cases. It is a matter of common experience now that whenever wheat is pickled with dry Copper Carbonate power in a shed or barn enough of the finer particles of copper carbonate settle on the inside of the building to kill all weevils, and the structures remain free from the pest. The dusting of the insides of shed with finely powdered copper carbonate, through a dust-gun, would eradicate the pest, and as only a small quantity of the powder would be necessary, no harmful effects to grain stored in the sheds would result. Weevils in grain can be killed by shooting the grain into bins which can be made air-tight, and then pouring carbon bisulphide into a basin resting on the top of the grain and closing the lid of the bin. About 4lbs. to 5lbs. of carbon bisulphide are sufficient for 1,000 cub. ft. of air space, and when calculating requirements allowance is made for the grain present.

The average production of dairy cows in Great Britain is 574 gallons of milk a year; in Denmark, 571 gallons; Germany, 520; Norway, 445; Australia, 290 gallons.

THIS SHOWS THE URGENT NECESSITY FOR IMPROVING METHODS OF FEEDING IN AUSTRALIA WITHOUT DELAY.

TENTH AND CONCLUDING REPORT ON THE TURRETFIELD DEMONSTRATION FARM (1921-32) INCLUDING DETAILED ANALYSIS OF MEAN FARMING COSTS OVER THE SAME PERIOD.

[By ARTHUR J. PERKINS, Director of Agriculture.]

PART I.

FINANCIAL ASPECTS.

1. DETAILS OF THE SCHEME UNDER WHICH THE FARM HAS BEEN WORKED.

In 1921 the Government of the day decided that the Turretfield Farm should be run upon business lines, that is to say, from its own revenues, and without the assistance of a State grant, but subject to overdraft rights not exceeding £2,200. Towards this end, Land and Improvements were valued by the State Land Board, and an independent valuation was made of Stock and Plant. The combined Capital Value of Land, Improvements, Stock, and Plant was finally assessed at £17,590 18s. 2d., upon which sum, apart from repayments, we have had to pay interest to the State Treasury at the rate of 5 per cent., *i.e.*, £879 10s. 11d. per annum. In addition to the above we have paid 6 per cent. on overdraft Balances. In 1924-25 we had a favorable season, combined with high prices for farm produce, and were able to reduce the Loan Account by £1,000 and were allowed corresponding reduction in interest charges.

It must be stated here that relatively to the manner in which the business of Farming is conducted in South Australia generally, Turretfield under the above arrangement was placed in an exceedingly unenviable position. In the first place it had to be run upon 100 per cent. Loan Money, interest upon which had to be paid regularly into the Treasury, and secondly, from the Manager downwards it had to be worked by a salaried staff, and was therefore without the stimulant of home labor. In the circumstances it speaks volumes for the management that over the first 6¾ seasons we should have been able to close the Farm Accounts on regular Credit Balances aggregating £2,748 18s. 3d., or an average of £407 4s. 11d. per annum.

Between 1928-29 and 1931-32, inclusively, on the other hand, *i.e.*, during four successive seasons, our Farm Accounts closed on Debit Balances, aggregating £4,371 7s. 5d. Hence, under the influence of unfavorable seasons and falling prices, not only were the Profit Balances of seven seasons wiped out, but in addition the transactions of 10¾ seasons closed eventually on a Debit Balance of £1,622 9s. 2d., as shown in the accompanying Balance-Sheet. It follows that after regularly meeting our obligations for 10 years we were obliged in 1931-32 to default in the matter of interest owing to Government for the year to the extent of £601 15s. 6d.

Briefly, the financial transactions of these 10¾ years admit of being summarised as follows:—

	£	s.	d.
1921-32 Inclusive Farm Expenditure	32,815	14	0
Less 1921-32 Farm Revenue	32,213	18	6
Debit Difference	601	15	6
Add Inventory Differences	1,020	13	8
1921-32 Net Loss	£1,622	9	2

I shall point out that in a Total Expenditure of £32,815 14s. was included £9,426 0s. 5d. representing moneys paid into the Treasury for interest on Loan Account and Overdraft (including £601 15s. 6d. in which we made default). Hence, interest charges have represented 28.72 per cent., or more than one-quarter of inclusive expenditure. This heavy drain on Farm resources is attributable to the fact that we had been placed in the abnormal position of working a farm on 100 per cent. borrowed money. A fairer arrangement, or, at all events, a more normal one, would have been to place us in the position of a farmer who had been able to find 50 per cent. of the Capital required, and had met the balance by means of a Mortgage. In such circumstances, instead of paying out £9,125 19s. in the way of Interest on Loan Account, we should have paid £4,562 19s. 6d. only; and whilst in such circumstances our actual Loss at the end of the 1931-32 Season would from a Bookkeeping standpoint have been no less great, we should still have had in the neighborhood of £3,000 towards tiding us over the period of low prices.

As matters stood, it was impossible for us to continue, and accordingly I recommended to my Minister that the present arrangement for running the Farm be discontinued, and eventually this was done.

Hence, the present is the last report on the Turretfield Demonstration Farm, together with the detailed record of Farming Costs incurred on this Farm.

2. BRIEF STATEMENT OF FARMING PRACTICES ADOPTED.

Apart from 71 acres of useless River bed, the net available Farming Area was represented by 1,533 acres, distributed as follows:—

	Acres.	Percentage.
Arable Land	1,266	82.6
Non-arable grazing Land (mostly hilly)	252	16.4
Buildings, yards, plantations, etc.	15	1.0
Total Available Farming Area	1,533	100.0

During the 11 years that Turretfield was worked under the conditions indicated above, a three-course Rotation, including—(1) Bare Fallow, (2) Wheat, and (3) a grazing crop (usually Oats) or natural pasture—was usually adopted, coupled occasionally with a two-course Rotation involving Pease and Wheat. In the earlier years the bulk of the Wheat crop was cut for Hay, but when with the gradual disappearance of the City demand for chaff, Hay growing became unprofitable, no more was subsequently cut at Turretfield than was actually required for Farm use. Originally Pigs and a small Dairy Herd were associated with arable farming; eventually, however, in the absence of home Labor both had to be abandoned and their place on the Farm was taken by a Fat Lamb Flock.

3. GENERAL SEASONAL CONDITIONS.

In the main, in this State, general Seasonal Conditions controlling Farm Crops are determined by the yearly Rainfall and its distribution over that part of the year—April-November—during the course of which Winter-sown crops make their growth. Turretfield Rainfall Statistics for the 11 seasons have been summarised below in Table I.:—

TABLE I.

Summarising 1921-31 *Turretfield Rainfall Distribution.*

Seasons.	Late Summer and Autumn Rains, Jan.-March.	Seeding Rains, April-May.	Winter Rains, June-July.	Spring Rains, Aug.-Oct.	Early Summer Rains, Nov.	Harvest Rains, Dec.	"Useful" Rains, April-Nov.	Yearly Rainfall.	Mean Wheat Yield per Acre.
	In.	In.	In.	In.	In.	In.	In.	In.	Bush.
1921 ..	3·87	3·26	2·84	6·05	1·92	1·56	14·07	19·50	—
1922 ..	1·52	4·69	5·32	4·33	—	2·76	14·34	18·62	15·08
1923 ..	0·46	6·10	7·76	7·96	0·41	2·42	22·23	25·11	9·93
1924 ..	3·88	2·41	3·09	8·22	2·19	0·22	15·91	20·01	23·91
1925 ..	1·19	3·39	3·11	6·38	0·58	0·05	13·46	14·70	23·42
1926 ..	0·94	3·33	3·85	7·76	0·82	0·41	15·76	17·11	19·33
1927 ..	1·47	2·32	3·51	3·85	1·55	1·32	11·23	14·02	21·27
1928 ..	4·17	2·42	3·91	4·01	0·09	0·30	10·43	14·90	18·38
1929 ..	0·79	1·29	3·22	4·10	1·42	2·62	10·03	13·44	17·47
1930 ..	0·47	1·78	3·84	6·78	0·72	0·36	13·12	13·95	18·79
1931 ..	0·97	3·42	5·25	6·05	0·19	0·09	14·91	15·97	20·35
Means	1·79	3·13	4·15	5·95	0·90	1·10	14·13	17·02	19·49

Of the above seasons, one—1923-24—was excessively wet, with the result that all of the land fallowed in the preceding season could not be sown and the mean yield per acre—9.93bush.—was the lowest in the series. On the other hand, 1929-30 and 1930-31 were dry and low yielding seasons.

4. CLOSING BALANCE-SHEET.

The attached closing Balance-sheet shows that after deduction of £3,126 for depreciation on Improvements and Plant on the one hand, and allowance for Interest charges of £9,426 on the other, the 11 years' farming operations at Turretfield closed for reasons already given on a Debit Balance of £1,622 9s. 2d.

For purposes of comparison the mean prices realised in each season for main saleable products—Wheat, Wool, and Fat Lambs—have been shown in Table II. in juxtaposition with Credit or Debit Balances of each corresponding season.

TABLE II.

Setting out Mean Prices realised for Main lines of agricultural Products in contrast with respective Credit or Debit Balances.

	Yearly Balances.	Mean Prices Realised.		
		Wheat per Bushel.	Wool per Lb.	Fat Lambs per Head.
	£ *s.* *d.*	*s.* *d.*	*d.*	£ *s.* *d.*
	Profit Balances.			
1921-22	398 11 6	4 8	4·3	0 14 2
1922-23	483 15 9	4 10	7·5	1 4 4
1923-24	215 5 11	4 1	19·5	1 6 3
1924-25	1,173 15 10	6 0	15·6	1 10 4
1925-26	79 5 2	5 9	12·4	1 2 2
1926-27	101 1 7	5 6	13·3	0 18 10
1927-28	296 2 6	5 4	17·1	1 2 10
	Debit Balances.			
1928-29	530 12 3	4 9	12·7	1 5 1
1929-30	757 5 0	4 7	6·3	1 1 11
1930-31	2,697 17 11	1 9	4·8	0 15 1
1931-32	385 12 3	3 4	7·6	0 13 6

There are two seasons which stand out in the above Table, 1924-25, in which weather conditions were exceptionally favorable, and Wheat yielded close on 24bush. to the acre on the one hand, and on the other Wheat realised 6s. a bushel, Wool 15½d. a lb., and Fat Lambs £1 10s. 4d. a head; this season closed on a Credit Balance of £1,173 15s. 10d. The other outstanding season was 1930-31, which closed on a Debit Balance of £2,697 17s. 11d.; weather conditions were relatively unfavorable, resulting in a mean yieled for Wheat of 18¾bush. to the acre. The price realised for Wheat was 1s. 9d. per bushel only, for Wool 4¾d. per lb., and for Fat Lambs 15s. 1d. per head.

In this connection it must be pointed out that the reduced value of commodities we had for sale was not the only way in which the general fall in prices affected our more recent Balance-sheets. The Fat Lamb Flock, exclusive of Rams, had to be written down on March 31st, 1930, from 27s. 9d. to 19s. a head, representing an aggregate loss of £431 for the season. Again, on March 31st, 1931, values were reduced to 16s. 6d., representing an aggregate Loss of £620 19s. since 1929. Hence, in the course of two successive seasons, the Per Head value of the Flock was reduced by 11s. 3d. or over 40 per cent. of the original value.

5. RATE OF INTEREST EARNED BY CAPITAL ENGAGED AT TURRETFIELD.

If, from the standpoint of a farmer working a farm mainly on borrowed capital, we look upon the funds engaged in Turretfield as being represented by the original State advances, namely, £17,590 18s. 2d., plus net profits, if any, and less part repayment of original Loan, then the rate of interest earned by the farmer in each successive season would have been as indicated in Table III.

TABLE III.

Showing Rate of Interest per annum earned by Capital invested in Turretfield Demonstration Farm in each successive season.

	Capital Engaged in Farm.		Farm Net Earnings.		Rate of Interest Earned.
	Total.	Per Acre.	Total.	Per Acre.	
	£ s. d.	£ s. d.	£ s. d.	s. d.	%
1921-22	17,590 18 2	11 9 6	1,019 12 7	17 9	7·73
1922-23	17,989 9 8	11 14 8	1,306 19 7	17 1	7·27
1923-24	18,473 5 5	12 1 0	1,094 8 10	14 3	5·92

NOTE.—In the above Table "Farm Net Earnings" are taken to represent Farm Gross Revenue, less costs, but exclusive of interest on Capital or Overdraft.

6. MANAGEMENT AND LABOR INCOME.

The earnings of Capital as set out in Table III. do not interest the farmer so much as his personal earnings, or what has come to be known as his "Management and Labor Income." In attempts at determining this "Income" the position is usually complicated on the average farm by the use of unpaid family labor. Actually the "Management and Labor Income" of a Farmer can be described as the difference between Gross Farm Revenue and Expenditure, inclusive of interest and depreciation charges, plus an estimate of the value of unpaid home Labor, but exclusive of any charge for the Farmer's personal Management and Labor. Towards this end we shall be able to make use of Table III. in order to determine what would have been the mean value of the "Management and Labor Income" of a Farmer had Turretfield been run as a private Farm.

The "Net Farm Earnings" of Table III. have been defined as "Farm Gross Revenue" less "Farm Expenditure," but exclusive of Interest on Capital or Overdraft, and the Mean "Net Farm Earnings" for 10¾ years were shown to have been £671 5s. 2d. per annum. On the other hand, in the "Mean Farm Expenditure" which was deducted from "Gross Revenue" was included a sum of £1,154 10s. 1d., representing mean cost of Management and Labor at Turretfield. If we add the cost of Management and Labor—£1,154 10s. 1d.—to Net Farm Earnings—£671 5s. 2d.—we get £1,825 15s. 3d., which can be taken to represent the Net Earnings of a Farmer, his family, and his Capital if we assume that he used no hired Labor. On the other hand, if we look upon mean interest charges—£876 16s. 9d.—as the earnings of his Capital and deduct the latter from £1,825 15s. 3d. we shall have £948 18s. 6d. as representing the mean Management and Labor Income of the Farmer and his Family, on the assumption that no hired Labor were engaged. Finally, if from the latter figure we deduct £827 6s. 8d., *i.e.*, the Mean Cost of Wages at Turretfield apart from the Manager's Salary, and which we shall assume to be the value of unpaid Family Labor, we shall get £121 11s. 10d. as the Mean value of the Farmer's Management and Labor. This low figure is brought about by the Losses incurred over the last four seasons, when the Mean Value of "Management and Labor Income" was actually a negative figure of £824 15s. 8d. In the preceding seven years the Management and Labor Income was positive and represented by £682 8s. 2d.

7. INTEREST ACCOUNT.

In the statements appearing in the second part of this Report, in which it is sought to determine inclusive "Costs" of various farming operations, interest charges are derived from two sources, namely:—

(1) Interest on original Loan, less repayments, plus interest on Overdraft, and

(2) Interest on accumulated Net Profits, if any.

The position of interest to be distributed among the various Real Accounts in each season is shown below in Table IV.:—

TABLE IV.

Showing Interest Paid or Debited in each Season.

Seasons.	Interest Due on Government Loan and Overdraft.	Interest Debited on Accumulated Net Profits.	Total Interest Debited Against Farm Accounts.
	£ s. d.	£ s. d.	£ s. d.
1921–22 (9 months)	659 5 0	—	659 5 0
1922–23	874 0 10	19 18 7	893 19 5
1923–24	928 16 7	44 2 4	972 18 11
1924–25	901 6 4	54 18 8	956 5 0
1925–26	845 0 3	113 12 5	958 12 8
1926–27	872 1 7	117 11 8	989 13 3
1927–28	872 16 4	122 12 9	995 9 1

1931–32	928 18 10	—	928 18 10
Total Interest Charges	9,426 0 5	794 4 9	10,220 5 2
Mean Charges per annum	876 16 9	73 17 8	950 14 5

8. DEPRECIATION ACCOUNT.

In Table V. below data have been summarised relative to Depreciation Deductions from Capital since 1921:—

TABLE V.

Summarising Depreciation Deductions from Capital, 1921-32.

	Buildings.	Fences.	Water Service.	Tools and Plant.	Total.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Original 1921 valuation	2,388 10 0	990 0 0	79 10 0	724 10 0	4,182 10 0
Subsequent additions	415 14 10	457 15 5	177 17 2	1,752 0 2	2,803 7 7
Totals	2,804 4 10	1,447 15 5	257 7 2	2,476 10 2	6,985 17 7
Less Sales and transfers	10 3 11	88 12 9	—	90 0 3	188 16 11
Original values	2,794 0 11	1,359 2 8	257 7 2	2,386 9 11	6,797 0 8
Less 1921-32 depreciation	696 2 6	745 9 5	98 5 7	1,586 12 0	3,126 9 6
1932 valuation	2,097 18 5	613 13 3	159 1 7	799 17 11	3,670 11 2
1921–32 Depreciation	696 2 6	745 9 5	98 5 7	1,586 12 0	3,126 9 6
Percentage of capital assets, plus additions, less sales	% 24·9	% 54·8	% 38·2	% 66·5	% 45·9

The statement (Table V.) shows that during the 10¾ seasons we have written down Capital Assets by £3,126 9s. 6d., or nearly 46 per cent. of original values. It is sometimes urged that Farmers' Balance-sheets should take account neither of Interest nor of Depreciation. If we had followed this suggestion our 10¾ years' transactions would have closed at an apparent profit of £10,930 instead of an actual Loss of £1,622.

9. HOUSE-KEEPING ACCOUNT.

The Farm has been responsible for the Board of the Manager, his family, and portion of the Farm Staff. In Table VI. below the mean Costs of 10 years' house-keeping have been summarised:—

TABLE VI.

Summarising Mean 1922-32 *House-keeping Costs.*

Items.	Total Costs. £	*s.*	*d.*	Percentages.
Labor	79	15	5	26·1
Provisions	101	10	0	33·2

PART II.

DETAILED ANALYSIS OF FARMING COSTS.

1. CAPITAL ACCOUNT.

It is obviously of importance to know the Capital Outlay required for farming in our Central and Lower North Districts. I propose, therefore, examining this question in detail from the experience of eleven years' farming operations at Turretfield.

It should be observed that on any Farm the Capital engaged is liable to vary from year to year; assets depreciate progressively; new purchases are made; and old implements may be sold. At Turretfield the value of Capital engaged has been represented successively by—

(1) the value of Government 1921 original advances, representing Land, Improvements, Original Stock and Plant, &c., less such repayments as may have been made towards reduction of these advances, and

(2) the value of such purchases as may have been made since 1921, together with accumulated Net Profits, which, whilst they lasted, have been treated as Turretfield Personal Capital.

Detailed analysis of the Capital Account on the 1st of July, 1921 (original), and on the 1st April, 1931 (closing), is shown below in Table VIII., together with corresponding mean figures for the 1921-31 period.

TABLE VIII.

Detailed Analysis of Capital Account, 1921-31.

	Capital, July 1st, 1921.	Capital, April 1st, 1931.	Mean 1921-31 Capital.

Sundries	438 14 8	171 18 11	292 15 11	0 3 10.	1·6
Floating Capital .	3,353 18 2	3,420 0 2	5.323 7 9	2 14 10	23·0
Total Gross Capital.	—	17,373 9 1	19,405 11 8	—	—
Less Cash Balance	—	2,019 7 10	1,028 9 11	—	—
	—	—	18,377 1 9	—	—
Less Repayment of Principal	—	—	90 18 2	—	—
	17,590 18 2	15,354 1 3	18,286 3 7	11 18 7	100·0

NOTE.—In the penultimate and last columns of the above Table 8s. 11d. per acre for Produce on hand, and 3.7 per cent. of the Mean Net Capital do not correspond to the figure of the immediately preceding column for mean Total Produce on hand, namely, £1,804 15s. 10d. Obviously, Total Produce on hand on the 1st April of any one year must vary within very wide limits, according to circumstances; the whole of the preceding year's Wheat Crop might, for instance, still be on hand, or, again, the bulk of it might have been sold. Hence, in order to avoid the existence of Cash Balances, in determining Capital per acre and percentages of Total Capital, the mean Debit Cash Balance of £1,028 9s. 11d. and the instalment of repayment of Principal—£90 18s. 2d.—have been deducted from the value of Produce on hand—£1,804 15s. 10d.—and the per acre and percentage figures have been calculated from the difference, namely, £685 7s. 9d.

The various items included in 1921-31 Mean Capital per acre admit of being summarily grouped together, as follows:—

	Value per Acre. £ s d.	Percentage.
Land and Improvements	9 3 9	77.0
Tools and Plant	0 15 2	6.4
Working Horses	0 5 6	2.3
Revenue Earning Live Stock	0 14 7	6.1
Farm Fallows	0 6 10	2.9
Sundries	0 12 9	5.3
	£11 18 7	100.0

2. MEAN INCLUSIVE COSTS OF FARMING OPERATIONS AT TURRETFIELD (1922-32).

Apart from the question of the original Capital essential to the acquirement and equipment of a farm, it is of equal importance to know the extent to which a farmer is likely to be involved in Cash expenditure, or corresponding Credit, for the yearly working of his Farm. Towards this end I have summarised in Table IX. mean inclusive expenditure per annum incurred at Turretfield during 10 successive seasons:—

TABLE IX.

Summarising Turretfield Mean Yearly Expenditure (1922-32).

	Total.	Per Acre.	Percentage.
	£ *s.* *d.*	£ *s.* *d.*	%

10. Interest on Loan and Overdraft	164	16	7	0	2	1·8	4·1
Totals	2,492	3	3	1	12	6·2	61·7
Totals of Items involving Cash Expenditure	3,070	6	0	2	0	0·7	76·0
II. ITEMS NOT INVOLVING CASH EXPENDITURE.							
1. Farm Produce fed to Livestock	603	19	10	0	7	10·6	14·9
2. Farm Produce used by Household	63	12	1	0	0	9·9	1·6
3. Farm Grain used for Seed	223	0	7	0	2	10·9	5·5
4. Interest on Personal Capital	79	8	6	0	1	0·4	2·0
Totals	970	1	0	0	12	7·8	24·0
Mean inclusive Yearly Expenditure	4,040	7	0	2	12	8·5	100·0

I shall draw attention to the following points in the above Table:—

1. Over 10 consecutive seasons inclusive expenditure incurred at Turretfield has been at the mean rate of £4,040 7s. per annum.

2. Of this sum £3,070 6s., or 76.0 per cent., involved actual Cash Disbursements, whereas £970 1s., or 24.0 per cent. may be taken to have been Book-keeping entries and transfers.

3. In the above statement Management and Labor has been assessed at £900 14s. 7d. To this sum, however, should be added £226 12s. 1d., representing value of provisions consumed by employees, plus rent of cottages occupied by them. This addition raises inclusive value of Management and Wages to £1,127 6s. 8d. per annum, or 14s. 8d. per acre, or, again, 27.9 per cent. of mean yearly expenditure. If from this sum we deduct the mean Loss per annum registered for these 10 years, namely, £257 0s. 9d., we shall get £870 5s. 11d., which would represent the Mean Management and Labor Income that would have been earned by a Farmer and Family, had they been mainly responsible for all manual operations.

4. This mean inclusive farm expenditure admits of grouping, as follows:—

	1922–32 Expenditure. Per Acre.	1922–32 Expenditure. Percentage.
	s. *d.*	
1. Management and Labor (including Provisions)	14 8	27·9
2. Buildings and Improvements (exclusive of Labor)	0 6	0·9
3. Upkeep of Plant (including Horses)	2 10	5·3
4. Purchase of Sheep and other Livestock	4 5	8·4
5. Livestock Foodstuffs	8 3	15·7
6. Manures	2 2	4·1
7. Seed	3 9	7·1
8. Sundries	2 11	5·5
9. Rates and Taxes	0 9	1·4
10. Interest on Capital and Overdraft	3 2	6·1
11. Interest on Land Value	9 3	17·6
	52 8	100·0

Expenditure involving Cash Payments, 40s.

By way of conclusion I shall merely draw attention to the fact that whereas interest charges absorbed 12s. 6d. per acre, or 23.7 per cent. of total expenditure, rates and taxes, concerning which so much is often heard, were responsible for 9d. per acre, or 1.4 per cent. only of total expenditure.

3. MEAN GROSS FARM OUTPUT.

It is, of course, obvious that if a Farm, the Management and Labor of which has to be met in hard Cash, is to continue operations, it is essential that the mean value of the gross farm output should exceed slightly the mean expenditure figures. The position as to mean output at Turretfield is shown below in Table X.:—

TABLE X.

Summarising Value of Turretfield Mean Gross Output per Annum (1922-32).

	Sold or Used.	Differences of Opening and Closing Inventories.	Mean Gross Output.

Mean Farm Gross Output Per Annum	4,036 3 7	−252 17 4	3,783 6 3	49 4	100·0
Add Mean Net Loss	—	—	257 0 9	3 4	
Inclusive Mean Expenditure	—	—	4,040 7 0	52 8	

It has already been stated that owing to a succession of indifferent seasons, and particularly owing to the disastrous drop in prices for rural products, operations at Turretfield had to cease at the end of 10¾ years. Table X. shows that in the last 10 years Expenditure exceeded Revenue by £257 0s. 9d. per annum (inclusive of rates and taxes). From the standpoint of a farmer, and particularly one who had the assistance of Home Labor, the position would not have been so critical. I have already shown that the Farmer and Family, responsible for all normal operations, would have had £870 5s. 11d. per annum as Management and Labor Income; such a sum would leave ample margin for the payment of casual Labor as required. In such circumstances there would have been no loss to register, even after payment of all interest dues and making adequate allowance for depreciation of Assets.

It will be observed that the mean yearly output at Turretfield, 17 per cent. to 18 per cent. of which consists of hilly, non-arable land, was represented by £3,783 6s. 3d., or 49s. 4d. per acre on the total area. Towards this Total, Harvested Crops contributed £2,347 15s. 1d., or 30s. 8d. per acre or, again, 62.2 per cent. of total output; Live Stock £1,362 17s. 8d., or 17s. 9d. per acre, or, again, 36.0 per cent. of total output; and Miscellaneous £72 13s. 6d., or 11d. per acre, or, again, 1.8 per cent. of total output.

4. VALUE OF OUTPUT AT TURRETFIELD OF AREAS CROPPED AND AREAS GRAZED RESPECTIVELY.

From data summarised in Table X. it is possible to determine fairly accurately the Mean Yearly value of output secured during 10 successive seasons from land concerned with harvested crops only on the one hand, and from land concerned with grazing Live Stock (chiefly Sheep) only on the other. Such information is of value in any attempt to assess the relative income earning importance of Crops or Live Stock on a mixed farm of the Turretfield type.

During these 10 years the mean area under Harvested Crops was 549 acres, and the mean area treated as Bare Fallow 438 acres; hence, the mean aggregate area allotted to Harvested Crops has been 987 acres. It must be recognised, however, that these 987 acres have not been actively concerned with Crops for more than nine months in any one year, and that over the balance of the year they have been available for grazing purposes, either as stubble grazing or as natural pasture. It follows, therefore, that on a per annum basis these 987 acres are in actual fact equivalent to no more than 740 acres exclusively devoted to Harvested crops, and leaving the equivalent of 247 acres per annum available for grazing purposes. From the latter standpoint a mean output of £2,347 15s. 1d. from Harvested Crops would be equivalent to a return of £3 3s. 5d. per acre from land exclusively devoted to Harvested crops during the year.

On the other hand, the mean yearly area available for grazing purposes may be said to consist of the following fractions:—

(1) 247 acres, namely, the yearly grazing equivalent of 987 acres under Crop or Bare Fallow for nine months in the year, but available for grazing over the remaining three months.

(2) 279 acres of arable land temporarily out of cultivation or sown to grazing crops, and

(3) 252 acres of non-arable land.

Hence, over 10 successive seasons the mean area available for grazing at Turretfield has been equivalent in the aggregate to 778 acres.

The mean Value of Gross Output from Live Stock has been shown in Table X. to have been £1,362 17s. 8d. per annum; but, since over this period foodstuffs have been fed from time to time to normally grazing Live Stock, this output cannot be put down wholly to the credit of areas available for grazing; and the mean value of foodstuffs fed—£245 13s. 1d.—must be deducted therefrom, leaving £1,117 4s. 7d. to the credit of the grazing area. On the other hand, this Output must be increased by the agistment value of Working Horses, which had occasional access to the grazing areas, namely, £40 16s. 8d. Hence, the final Net Value of the Mean Output of that portion of the Farm exclusively grazed was represented by £1,158 1s. 3d., or £1 9s. 9d. per acre per annum, as against £3 3s. 5d. per acre per annum for land exclusively devoted to harvested Crops.

The following statement shows a rough approximation of differences between Revenue and Expenditure on cropped and grazed areas respectively:—

	Area Devoted to Crops.		Area Devoted to Grazing.	
	s. *d.*	£ *s.* *d.*	*s.* *d.*	£ *s.* *d.*
Mean Expenditure per Acre—				
1. Interest on Land and Improvements ..	10 5·5		8 4·2	
2. Interest on Working Capital	4 8·5		1 9·6	
3. Rates and Taxes	0 10·0		0 7·6	
4. Wages	21 2		8 10·4	
5. Other Expenditure	32 2		13 1·2	
		3 9 4		1 12 9
Mean Output per Acre		3 3 5		1 9 9
Mean Loss per Acre per Annum		0 5 11		0 3 0

Thus, then, as a result of a succession of unfavorable seasons, and recent unprecedented fall in prices of rural products Turretfield Losses over 10 years (1922-32) have been at the rate of 5s. 11d. per acre for areas devoted to crops, and 3s. per acre for areas devoted to grazing. It is necessary, however, to point out that a Farmer who employed little or no hired Labor would have been very differently situated; in effect his accounts would have shown no losses, and after meeting all interest and depreciation claims he would have received for Management and Labor 15s. 3d. per acre from Land devoted to Crops, and 5s. 10½d. from Land devoted to grazing, *i.e.*, about 10s. 5d. per acre on the area farmed.

5. INITIAL CAPITAL REQUISITE TO THE SUCCESSFUL WORKING OF A 1,000-ACRE FARM OF THE TURRETFIELD TYPE.

It will probably be recognised in this connection that apart from the position of the average man working in an average season, the minimum initial Capital requisite to the successful working of a Farm would depend upon three main factors, namely:—

(1) Individual capacity. (2) Seasonal conditions over opening years, and (3) Current market prices over the same years. In other words, if an individual farmer should have high technical capacity, coupled with business acumen above the average, if in the opening years of operations he should have the advantage of seasonal conditions and market prices above normal means, it is highly probable that this exceptionally favored individual would be in a position to start farming on a minimum personal Capital that would lead to disaster the average man facing unfavorable or even average conditions only. In the development of a new country, it is, however, inevitable that such implied risks should frequently have been taken; and, unfortunately, in such cases failures have usually outnumbered successes, and not infrequently it has been the better provided or luckier successors

of the pioneers in land development who have reaped the crops that the latter have sown. But, in this connection, it is not my intention to try and determine what should be the minimum personal Capital upon which the exceptional man, facing favorable conditions, could afford to start farming, but rather to show from carefully recorded data of 10 successive seasons what personal Capital would have been essential to an average man facing normal conditions in order to work successfully a 1,000-acre Farm of the Turretfield type.

We must assume for the purpose a Farm of this character to be situated on the heavier land of our Central or Lower North Statistical Divisions, and to consist of from 820 to 830 acres of arable land, including 9 to 10 acres under Buildings, yards, plantations, &c., and 170 to 180 acres of rough grazing land. We shall also assume that a farmer seeking to acquire and work a farm of this type on a minimum of Personal Capital would be able to secure Mortgage and Loan facilities to the extent of two-thirds of the value of his Capital assets. Reference to Table VIII. will show that the Capital requisite to the purchase and equipment of such a Farm would be represented by £11 18s. 7d. pr acre, or for a 1,000-acre Farm approximately £12,000. In the circumstances, the minimum Personal Capital essential to the purpose would be in the neighborhood of £4,000, whilst £8,000 would represent the extent of Loan Liabilities, which at 5½ per cent. would involve total interest charges of £440 per annum, or 8s. 10d. per acre.

I shall now endeavor to show on the basis of 10 seasons' records at Turretfield —1922-32—the extent to which anticipated Revenue and Expenditure would justify farming operations on an initial Personal Capital, equivalent to one-third of the Capital engaged in the Farm.

Reference to Table IX. will show that Mean Yearly Expenditure at Turretfield involving Cash payment has been at the rate of 40s. per acre. In this figure, however, are included 11s. 9d. paid out in wages, to which should be added 2s. 11d. for provisions consumed by employees and rents of Cottages, and 11s. 5d. for interest charges per acre. On the Farm that we have in view interest charges involving cash payments have been assumed to be at the rate of 8s. 10d. per acre, and if, as is usually the case, the farm were worked almost exclusively by the farmer and his family, cash payments for wages would to all intents and purposes disappear. In lieu of the latter, however, provision would have to be made for the upkeep of the farmer and his family, and in these days I suggest £250 for the purpose, or 5s. per acre. Hence, in lieu of the Turretfield figure of 26s. 1d. per acre towards payment of wages and interest charges a sum of 13s. 10d. per acre should suffice on a farm worked mainly by a Farmer and his Family. It follows, therefore, that in such circumstances actual Cash outgoings need not exceed 27s. 9d. per acre instead of 40s., as at Turretfield; on a 1,000-acre Farm this would represent £1,387 per annum in the way of Cash outgoings, including the upkeep of the farmer and his family.

Again, reference to Table X. will show that at Turretfield the mean value of Farm Output per annum has been at the rate of £3,783 6s. 3d., or 49s. 4d. per acre; of the latter sum not less than £3,066, or 40s. per acre, have represented direct Cash receipts. Hence, in the circumstances already indicated, a Farmer working a 1,000-acre Farm of the same type should be able to anticipate a mean Farm Output of £2,467, of which not less than £2,000 would represent direct Cash receipts. Output on this scale would be more than adequate to meet estimated Cash Outgoings of £1,387 per annum, and in addition would make ample provision for unforeseen emergencies and occasional use of Hired Labor.

I conclude, therefore, that in competent hands a Personal Capital of £4,000 should suffice for the purchase, equipment, and working of a 1,000-acre Farm of the Turretfield type.

6. GENERAL EXPENSES ACCOUNT.

In any business undertaking, and in farming to a greater extent perhaps than in any other, numerous items of expenditure are incurred in the course of a year's operations which cannot readily be debited directly against any particular Real Account. In the aggregate these items of expenditure represent the overhead charges which must eventually be distributed among Revenue-earning Accounts, and usually in proportion to the monetary importance of each.

Mean General Expenses incurred at Turretfield during 10 consecutive seasons (1922-32) have been summarised below in Table XI.:—

TABLE XI.

Summarising Mean General Expenses per Annum Incurred at Turretfield (1922-32).

	Total.			Per Acre.		Percentages.
	£	*s.*	*d.*	*s.*	*d.*	
1. Interest on Floating Capital and Overdraft	244	5	0	3	2	36·6
2. Wages	219	16	3	2	10	33·0
3. Depreciation	78	6	3	1	0	11·7
4. Rates and Taxes	55	7	5	0	9	8·3
5. Sundries	45	0	8	0	7	6·8
6. Use of Implements	13	15	3	0	2	2·1
7. Use of Horses	9	16	5	0	2	1·5
Totals	666	7	3	8	8	100·0
Mean Yearly Total Expenditure	4,040	7	0	£2 12 8		—
Percentage of Total Expenditure	—			—		16·5

Thus, over a period of 10 years "General Expenses" at Turretfield have been at the mean rate of £666 7s. 3d. per annum, or 8s. 8d. per acre, or, again, 16½ per cent. of Total Yearly Expenditure.

The Mean Distribution of these "General Expenses" among Revenue-earning Crops has been as follows:—

TABLE XII.

Showing Mean Distribution of General Expenses Among Revenue-earning Accounts (1922-32).

(*To be continued.*)

THE CURRANT GROWING INDUSTRY IN SOUTH AUSTRALIA.

INVESTIGATION DESIGNED TO IMPROVE CERTAIN CULTURAL PRACTICES IN NON-IRRIGATED DISTRICTS.

[Work outlined by Mr. GEO. QUINN, Chief Horticultural Instructor.]

Subsequent to proposals placed before the Hon. Minister of Agriculture by the South Australian Dried Fruits Board expressing willingness to meet certain costs, Mr. Geo. Quinn (Chief Horticultural Instructor) recently stated that he had drawn up an outline of experimental and demonstrational work deemed desirable to effect an improvement in the quantity and quality of currants grown in the principal non-irrigated areas, which was submitted to, and accepted by, that body. He accompanied the members of the Board to well attended meetings of currant growers called by that body at McLaren Flat, Angaston, and Clare, on June 20th, 21st, and 22nd, respectively, and laid an outline of the proposed scheme before each meeting.

After full discussion, the growers at each centre, by resolution, agreed to co-operate in the work and elected a local Committee of three leading currant producers to represent them. Each of these Committees was asked to interview owners of vineyards in their respective districts who might be prepared to set aside small areas of vines for experimental purposes. It was also arranged that these areas would subsequently be inspected, and such as were deemed suitable would be selected by a joint Committee.

The general organisation for carrying out the investigation consists of the local Committee in each district; the owner of the vineyard; Mr. Julius Victorsen (representing the dried fruit growers in non-irrigated districts on the Dried Fruits Board); the District Horticultural Instructor; Mr. A. V. Lyon, M.Sc. Agric., Officer in Charge of the C.S.I.R. Viticultural Research Station, Merbein, Victoria; and Mr. Quinn.

The owner of the vineyard agreed to carry out all ordinary cultural practices, such as tillage, pruning, harvesting, cincturing, &c.; the District Horticultural Instructor will be responsible for seeing this is done, recording all data, and directing and assisting from time to time in such work as may require technical skill. In the above, he will confer with the local Committee in respect to local matters.

As it was the desire of the Board, Mr. Quinn discussed with Mr. Lyon (who agreed to co-operate in the work in an advisory or consultative capacity) the general plan of the work which had previously been placed before the growers, and they came to an agreement as to the procedure to be followed in carrying out the investigation. It was also agreed that Mr. Lyon should, in company with the Secretary of the Dried Fruits Board, the respective local Committees, Mr. Victorsen, the District Horticultural Instructor, and Mr. Quinn visit each of the suggested plots in each centre and select those deemed most suitable for the purpose. Owing to the demands this work was likely to make on the time of the Horticultural Division, it was agreed the programme should, at present, be limited to three principal and most urgent problems, viz.:—

(1) The reorganisation of the vines in old Currant vineyards.
(2) Testing the comparative values of Rod and Spur pruning, with Spur pruning only, and Spur pruning supplemented by disbudding unwanted shoots in the Spring.
(3) A study of crop yields in an average vineyard, preparatory to initiating a manurial test therein.

CLARE DISTRICT.

Mr. Quinn stated that in the Clare district a plot comprising some of the oldest and most debilitated currant vines in the district, and located in the rich, black alluvial soil of Stanley Flat, was accepted for reorganisation in Mrs. A. Dolan's vineyard.

In Mr. C. Neate's vineyard, on Stanley Flat, planted in alluvial soil of moderate strength, a series of plots of fair average vines will be tested for individual crop yields prior to initiating manurial trials. In Mr. W. H. Penna's vineyard, planted on hillside loam of good average quality, at Sevenhills, pruning test of Rod and Spur *versus* Spur, etc., will be undertaken. The vines in this vineyard are well trained, and being in good, healthy productive condition should prove well suited for the purpose.

ANGASTON DISTRICT.

In the Angaston district Mr. G. L. Wishart offered several rows of vines in his very old currant vineyard for renovation. Notwithstanding that they grow in deep loam, these vines have gradually dwindled in growth and production, although apparently quite healthy on the lower trunks below the cincturing scars.

In a healthy, productive, medium aged, well-developed vineyard growing on red sandy loam over clay, at Light's Pass, and belonging to Mr. P. B. Boehm, a suitable number of rows of vines have been secured for pruning tests, and a plot has also been set aside for conducting crop yield investigations in this vineyard.

McLAREN VALE DISTRICT.

In the McLaren Flat area, where nearly all the currant vineyards in this district are established, Mr. G. Bell has allotted a couple of rows of very old vines, planted in deep, sandy loam, for reorganisation work. He has also allowed the Committee to use three rows of well-trained, moderately vigorous, medium aged vines, growing on a sandy slope in soil typical of the locality for the purpose of conducting a pruning trial.

On the southern side of McLaren Flat Mr. A. C. Fraser has agreed to co-operate in the investigation by allowing preliminary crop yields to be taken in a portion of his fine vineyard. These vines, which are in full bearing and reflect careful attention in the past on the part of the owner, are growing in a good, strong sandy loam over clay.

After inspecting (in company with the local Committees) the vineyards made available in the respective districts, the work decided upon in those selected was discussed in each instance with the Committees and the owners in comparative detail. Each of the local Committees enthusiastically agreed to endeavor to arouse public interest in the local experiments and to appoint a Chairman and Secretary with a view to collecting and disbursing a small emergency fund to meet any unexpected or special expenditure on casual labor, if required, during any busy period when the owner may not be able to assist the District Horticultural Officer.

REORGANISATION OF OLD VINES.

In many of the older currant vineyards of this State most of the vines have become debilitated and economically unproductive. A critical examination reveals that the principal factors making for this condition arise, firstly, from the ill effects of faulty methods of training the permanent arms on the wire trellises; and secondly, from the devitalising influences exercised by the cincturing applied to the main stems annually over periods varying from 25 to 30 years. The faulty training consists in originally failing to establish and maintain the permanent arms of each vine on a common level, but a more serious error has been displayed in the manner in which these arms have been permanently twisted around the trellis wires. With accruing years these arms have developed into horizontal spirals, exhibiting huge dead lignified and sunken areas wherever the pressure of diverted growth attempted to envelop the wire. Needless to say, wherever such constrictions occurred, the outer end of the limb gave rise for a time to puny shoots, and eventually died.

Although vinegrowers have, for a period probably longer than the age of many of the vineyards, been warned of the evils to be expected to arise from these practices, it is only now being freely acknowledged to be a serious mistake.

The accumulative ill effects of the application of annual cincturing to the main stem of the currant vine have probably been much aggravated by the unsuitable tools frequently used, as well as by the drastic manner in which the cincture has been applied.

In the older currant vineyards in South Australia there is much support for the statement made by the late W. C. Grasby, in 1893, on his return from Greece, from whence he introduced and advocated cincturing as a means of inducing a more profitable setting of the berries on the Zante currant bunches. "In Greece," he stated, "the opinion was held that the annual cincturing of the stem reduced the profitable life time of the currant vine from 10 to 20 years—in accordance with the nature of the soil, situation, and general attention given to the plant."

As previously remarked, the bases of the stems of these old vines were reasonably sound, displaying in many instances either a wealth of adventitious buds or a scattering of watershoots, arising either just above or below ground level.

The rejuvenation to be undertaken will consist of removing the superstructure of these old vines, and leading up a watershoot to form a new stem to each one, and therefrom laying down new arms upon new trellis wires, which the owners are erecting at a greater elevation than that adopted for the old vines. The lessons from frost injuries and the ill effects of over shading the fruit, which occurs on low, crowded trellises, doubtlessly instigated this change.

Full data will be collected relative to the time taken to bring these reorganised vines back to a good standard of production, and compare the production with that of similar vines left untreated. It may be remarked incidentally that instances of growers who have taken, with gratifying success, the initiative in the above direction, are not wanting in several of the districts in which the Committee is operating.

PRUNING TESTS.

In practically all currant growing districts in this State—other than at McLaren Flat and Langhorne's Creek—the Zante currant vine is now Spur pruned. This is an evolution of practice, consequent upon the success attending the adoption of cincturing as a means of inducing a maximum setting of fruit.

The system of training adopted of late years for this vine is known as the Thomery Spalier, and modern practice indicates that a fairly high trellis is desirable when the vines are set on deep, strong land. On such a trellis alternate vines in a row are trained on the lower and higher wires respectively, each with a single pair of permanent arms. The spurs arising from these arms are carried to the third bud at their first pruning, and from thence outward by one or two buds each winter—according to their individual strengths—until short secondary arms of a semi-permanent character are developed. The result of this is to spread the frame on a horizontal plane and admit more light and air throughout to the foliage and fruit.

At the Berri Experiment Orchard, in the vine training and pruning plot, the rows of currant vines trained as cordons and spread over a T-piece trellis, and rod and spur pruned, have, over a 14-year period, produced the greatest weight of fruit borne by this variety under any form of training and pruning tested, but the fruit has been inferior to that borne on spur pruned spaliered vines in the same set of trials, which, it may be stated, are also not far behind them in gross yielding capacity.

It is proposed to test these phases of pruning by selecting in each district two or three rows of well-grown currant vines in good cropping condition—aggregating from 99 to 120 vines in all.

Discarding outside or terminal vines at each end of the row, the first vine under Treatment S will be spur pruned; the second, under Treatment SD, spur pruned and disbudded of all excess sprouts in spring; whilst the third, under Treatment RS, will be rod and spur pruned—the number of rods retained being determined each year in accordance with the strength of growths observed on the arms.

This order of treatment will be replicated from 30 to 40 times in each district plot, and each vine will be marked with a label indicating that vine's number and treatment in letters and figures.

The data to be collected will be:—

Treatment S: Total weight of fruit borne on each vine, the density of must, average size of berries, and drying ratio.

Treatment SD: Similar to S in all details.

Treatment RS: Similar to S, but separate data to be taken of the fruit borne on spurs and rods respectively.

If time permits, the prunings from the respective treatments may be collected and weighed, and possibly bud studies conducted on the canes. The comparative occurrence of seed bearing berries, "bucks," in the relative treatments will be observed and segregated if circumstances permit of drying the whole of the fruit gathered from each of the treatments separately.

CROP YIELD STUDIES (PRELIMINARY TO MANURING).

It was decided to collect over a period of several years crop data from 20 to 25 groups, each consisting of from four to six vines, the latter varying in accordance with the number of rows available in the plot placed at the Committee's disposal.

These groups are scattered in regular order throughout the rows of currant vines which have been selected because of standing in soil of reasonably even type displaying normal growth, and being subjected to fair average standard cultural treatment as followed in the district. Each of the selected groups is surrounded on all sides by rows of vines similarly treated, so that other than collecting cropping data no departure from ordinary procedure is anticipated.

The Vines in these groups will be individually and consecutively numbered from 1 to 150 with a small permanent label. The data collected will consist of recording the yield of each vine. With this data to hand it should be possible to assess the influence each of the present factors exercises in the production of the crop. By grouping the groups—based on the information the vines have supplied—the Committee may then formulate and test the values of certain manurial treatments.

It may be mentioned in conclusion, said Mr. Quinn, that a grower in the Angaston district (Mr. A. Thorn) has submitted an offer to the Committee to plant, as a demonstration plot, a small area of currant vines on lines which accumulated experience indicates as most desirable, and to submit them to methods of training, pruning, cincturing, tillage, &c., deemed to be most conducive to their permanent well being and productiveness. He is propagating the cuttings this year, so that, if his offer be renewed, the planting may take place in the winter of 1933.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

SIDELINES ON EYRE'S PENINSULA FARMS.

[By W. J. Spafford, Deputy Director of Agriculture.]

The judging of the competition for sidelines on Eyre's Peninsula farms inaugurated by the proprietors of the *Chronicle* newspaper, who also provided the prizes, was completed on October 29th, 1932. When arranging for the competition the donors had in mind the encouragement of increased production in dairying, pig raising, poultry keeping, fat-lamb breeding, and any other money-earning agricultural production except cereals and wool, and hoped that the increased production would lead speedily to the utilisation of the Port Lincoln Freezing Works or the erection and management of privately owned facilities for the handling of such products.

For the purposes of the competition, Eyre's Peninsula was divided into two districts, and the entries received in the Lower Eyre's Peninsula District were judged by the Agricultural Instructor for that district (Mr. H. D. M. Adams), whilst those received in the Upper Eyre's Peninsula District were judged by the Agricultural Instructor for that district (Mr. W. H. Brownrigg). These two judges chose what they considered the three best entries in their respective districts, and the writer judged these three entries to a set scale of points, and placed them in their order of merit, for each of the two districts:—

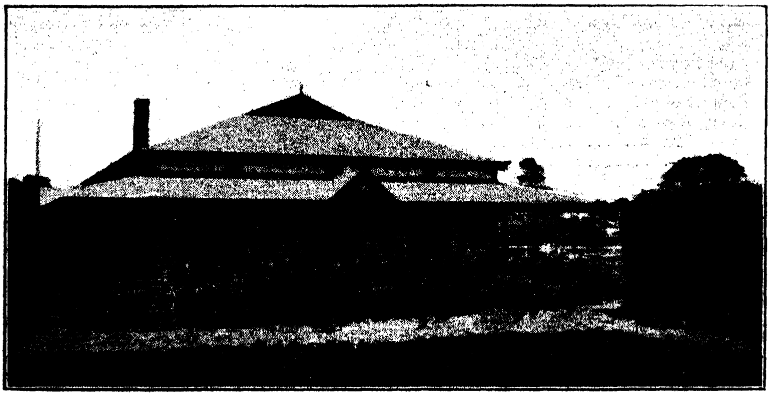
THE ENTRIES IN LOWER EYRE'S PENINSULA.

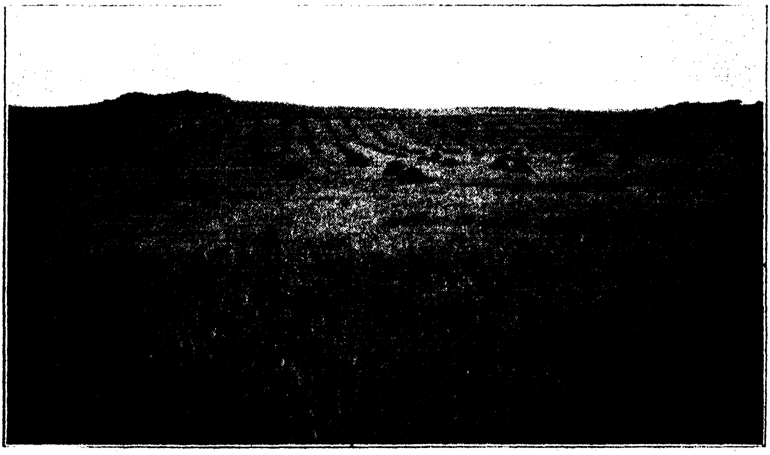
F. Masters, Verran.—The animals exhibited in the competition by Mr. Masters were a long way the best of those put before the judge, and this largely because of the fact that practically all animals kept on the farm have been pure bred, and Mr. Masters has always introduced pure-bred sires from the best flocks and herds in the State. The milking herd is comprised of six cows only, but they are good Jerseys. The heifers in the herd are much better than their dams and show the influence of the sire, a nicely furnished Jersey, which has just been replaced as head of the herd by an attractive herd-book Jersey recently introduced. For some years pure-bred Berkshire pigs have been kept, but Mr. Masters is now using a Large White boar of ideal type on his five Berkshire sows. Merino ewes of fair type are mated with Shropshire rams to produce fat lambs, the rams being of the very best of the breed. The Leghorn fowls, 200 in number, were all purchased from Parafield Poultry Station. Of other poultry, geese only are kept. Some tomatoes are sold each year, but this is the only form of sideline availed of other than livestock.

Because he has persisted in breeding pure-bred animals and has only used sires of good type and high quality, Mr. Masters is in the position of being ready to take advantage of the improved marketing facilities about to be provided for Eyre's Peninsula farmers, and his action in this direction is to be commended. All of his livestock are of good type and a credit to him.



Mr. H. C. Roediger has one of the nice homesteads of Yeelanna district.

Mr. H. C. Roediger, Yeelanna.—Although Mr. Roediger carries a lot of livestock on his farm his wheat growing and sheep flocks are so extensive that the sidelines only form a relatively small proportion of his farm activities. There are 20 cows in the milking herd, all being grade Shorthorns, but a young Jersey bull has been secured and he will soon be old enough to head the herd. Four half-bred Berkshire x Tamworth sows are used for breeding purposes, but are mated to a Berkshire boar of the old type. No attempt is being made to breed good fat lambs, but Corriedale rams have been mated to Merino ewes and the wether lambs are a great improvement on pure-bred Merinos. About 200 hens, comprised of Leghorns and Orpingtons, are kept, and are



A large field of King Island Melilot on the property of Mr H. Edwards, Streaky Bay, being converted into hay, estimated to yield over 1 ton to the acre.

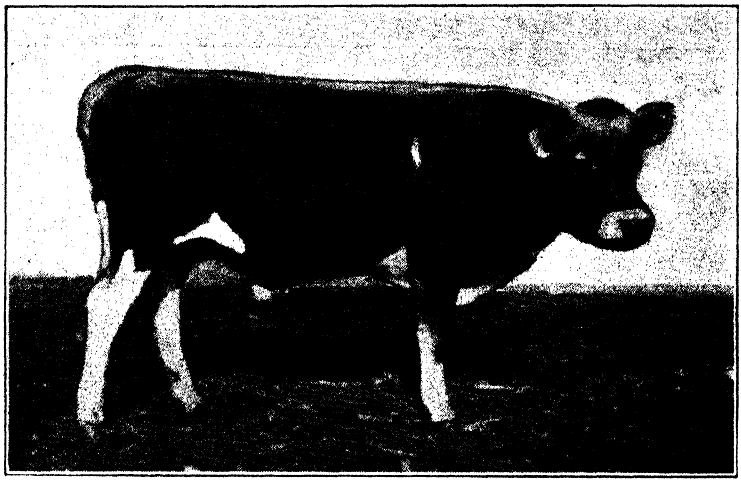
of quite fair type, the roosters used in the mating pens being pure-bred, but not from particularly good strains. Turkeys are the only other form of poultry kept, and of these there were 70 grown birds as well as numerous young ones. No other sidelines are produced and sold. A good dairy bull from high-production ancestors, a Large White boar of good modern type, and roosters of good laying strain would have a beneficial effect on the livestock of this farm.

A view of the homestead of Mr. H. Edwards, Streaky Bay.

Mr. W. Modra, Yeelanna.—Extensive crop growing and sheep carrying mean that the sidelines of Mr. Modra's farm form a relatively low proportion of his farming activities. The six cows in the milking herd are half-bred Jerseys of a useful type for milk production, but a noticeable improvement should take place with their progeny now that Mr. Modra has an attractive Jersey bull, by a subsidy bull out of a pure-bred cow. There are six half-bred Berkshire x Tamworth sows on the farm which are being bred to a Large White boar of fair type. A good Large White boar of modern type would produce first class bacon pigs from these sows. No fat lambs are being produced. About 100 barnyard fowls have the run of the farm, but fair quality Orpington

Mrs. W. Modra keeps her flower garden at Yeelanna in good order.

roosters are now being used to improve the flock. Other poultry consist of a couple of geese, a turkey, and a few Muscovy ducks. No other sidelines are produced for sale, although an extensive and attractive flower garden is maintained in excellent condition, and a fair collection of fruits and vegetables are well cared for.



Mr. F. Masters of Verran has recently introduced this attractive young Herd Book Jersey bull.

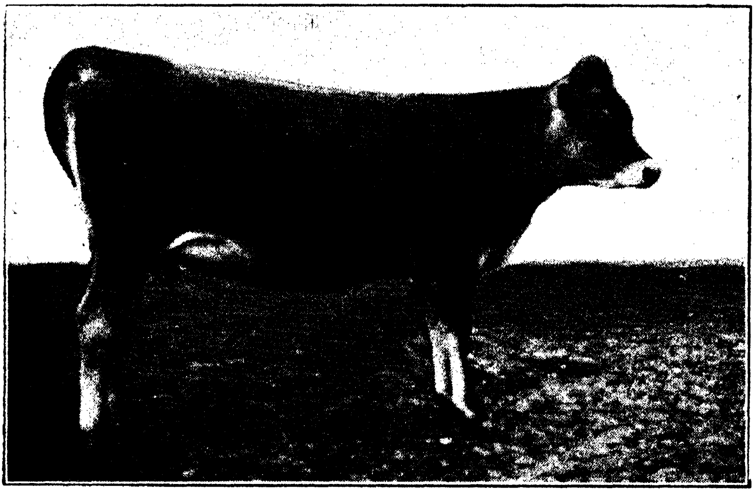
THE ENTRIES IN UPPER EYRE'S PENINSULA.

H. Edwards, Streaky Bay.—Although Mr. Edwards has 30 cows in milk, these and his other animals remain a sideline because his crop growing and sheep raising activities are so extensive. The cows are good grade Jerseys, but at the time of inspection were looking rather rough-coated and hide-bound, due to some unexplained reason, and so it was difficult to estimate their milk yielding capacity. The Jersey bull now at the head of the herd is from one of the best herds in the State, and in all probability will greatly improve the stock. Three Berkshire sows and one Mid-York are used for breeding purposes, and are mated to a Berkshire boar. The fat lambs produced are from Merino ewes by a Romney Marsh ram. About 120 Leghorn hens are kept in a 3-acre yard enclosed with 6ft. netting. White Leghorn roosters are used in the mating pens. Five geese and a batch of goslings, as well as some half-bred Pekin x Rouen ducks are also kept. A little market garden stuff and some figs are sold each year.

A. V. Preiss, Cleve.—Because of the extent of his other farming activities, sidelines do not form a high proportion of Mr. Preiss' operations. Seven high-grade Jersey cows of good quality are regularly maintained, and the recent introduction of a young herd-book Jersey bull with aristocratic breeding should further improve the heifers. Two Mid-York sows and one Berkshire are kept, but at the moment no boar is on the property, which shortage will soon be overcome, as Mr. Preiss has arranged to introduce a Large White boar to mate with his sows. Corriedale rams of good type are being used on Merino ewes to eliminate wrinkles from the ewes so bred, and the wether lambs are better meat animals than the pure Merinos. About 150 White Leghorn and Black Orpington hens have the run of the farm, but five breeding pens of pure-bred birds are in use. White Runner ducks to the number of 20 are kept.

E. J. Beinke, Kimba.—Only five cows are regularly kept in Mr. Beinke's milking herd, the animals being grade Shorthorns, the progeny of which should be considerably improved by the attractive looking Jersey bull now being used. Two Berkshire and two Berkshire x Tamworth sows are used for breeding, the boar being a Tamworth of very fair quality. Three Lincoln rams and a Corriedale are used on Merino ewes, the wethers being sold as lambs, and the ewe lambs are being kept to develop into mothers of fat lambs. Only 65 hens of the barnyard type, although mainly of Leghorn blood, are kept, and no other kinds of poultry are reared. Some fruit and tomatoes are sold in season.



A well-grown Jersey heifer belonging to Mr. E. J. Beinke of Kimba

J. W. Bartram, Kimba.—Because of a tie in the original judging, Mr. Bartram's sidelines were also inspected, but under the existing method of farming being practised, with the considerably reduced area under wheat, and none of it on fallow, the sidelines constitute more than the maximum proportion of farming activities allowed by the donors.

GENERAL.

The competition has shown that some Eyre's Peninsula farmers are alive to the value of good breeding in their livestock, and on the other hand it has also revealed that many do not recognise that there is a difference between the well-bred and the mongrel. Certainly there has been little encouragement to breeders to make much effort to improve their animals, and the handicap of lack of marketing facilities and the enormous expense of introducing sires from Adelaide side is very great. Now that it is becoming possible to market most farm sidelines at Port Lincoln under reasonable conditions the position has altered, and more attention can be paid to improving the farm animals.

Jersey cattle are doing really well throughout the Peninsula, and as good Jersey bulls—subsidy and other—are readily obtainable in South Australia, the procuring of one of guaranteed breeding for milk production will mean the producing of heifers a good deal better than their mothers in most cases.

Part of the herd of grade Shorthorn cows maintained by Mr. H. C. Roediger of Yeelanna.

There are plenty of strong, high-backed, deep-bodied sows on the Peninsula capable of breeding ideal bacon pigs, and they will probably do it with most certainty if mated to Large White boars of the modern type.

Most of the English breeds of sheep will produce good fat-lambs from large-framed, deep-bodied Merino ewes, but for nearly all portions of the Peninsula best results are likely to follow the use of Southdown, Ryeland, Border Leicester, Dorset Horn, or Suffolk rams in the order named.

Minorca fowls lay large eggs of attractive shape, and are good fowls on a farm, as are also White Leghorns and Orpingtons, but where the latter breed is concerned sittings of eggs, chickens or cockerels should always be procured from strains that lay large eggs.

The first essential towards success in improving animals is to use good sires, and on no account should any but pure-bred sires ever be used on farms.

SAVE AND PROFIT.

Piling shillings one upon another may be a form of thrift, but it is a risky method—and unprofitable. There is loss of profit because the same money, placed in a Commonwealth Savings Account, would earn interest. There is risk of loss by fire, by burglary, even by inadvertence, and, not so obvious, but quite definite, there is the risk of temptation to spend.

The Savings Bank Account is the logical place for your savings, for there they both accumulate and earn interest. Thus your saving power is multiplied, your savings become profitable, and you are less tempted to spend wastefully.

OPEN YOUR ACCOUNT NOW.

REVIEW OF THE AGRICULTURAL SEASON.

[By E. Bromley, Divisional Meteorologist, Adelaide, South Australia.]

The weather experienced over practically the whole of the agricultural areas during the seven months (April to October) has been of a favorable nature, and prospects point to a bounteous and probably record harvest.

The partial break in the season which occurred towards the close of March was completed early in April. Widespread rains marked the passage of a disturbance of monsoonal origin which drifted across the State early in the month, while another deep cyclonic system in the second week brought further heavy falls. Two more rain storms occurred in the second half of April, the month being generally a wet and cold one, with heavy rainfall excesses over the greater part of the agricultural areas.

May, on the other hand, was for the most part fine and mild, due to anticyclonic control. Monsoonal influences, however, became active early in the second half of the month, bringing opportune rains.

Apart from light to moderate rain at the beginning of June the early part of that month was fine, with mild days but cold, frosty nights. Wintry conditions, however, definitely set in on the 11th, when a well-placed disturbance yielded probably the best rain for the season. During the next fortnight an almost unbroken succession of low pressure waves brought daily rain of a light to moderate character, and a continuance of cold, cloudy, and squally weather. The latter part of the month was, however, fine with some very cold, frosty nights.

Except for brief fine intervals, July was unsettled with frequent rain, but the falls were chiefly light to moderate in character, and the totals somewhat below the average in Western and Upper North Districts.

More good rains took place in August, particularly during the first half, which was unsettled as the result of two energetic disturbances. A cold snap with some snow occurred at the middle of the month, followed by a week's fine weather with many frosts and fogs.

Chiefly as a result of monsoonal influences, which were most persistent, further useful rains fell in September, except over the Upper Murray and adjacent districts. Owing to the absence of energetic southern "lows" there were few strong winds, and at Adelaide it was the calmest September on record.

Tropical depressions, which at times developed cyclonic formation, were also active in October, and in consequence the weather was very cool, cloudy, and unsettled, with frequent rain accompanied by many thunderstorms. Taken on the whole the month's rainfall was slightly above normal, but in the Upper Murray the registrations were again only light.

"ABOVE AVERAGE RAINS."

With a few isolated exceptions the total rainfall for the seven months (April to October) was above the average throughout the agricultural areas, the surplus in the majority of cases ranging from 2in. to 5in. A few places, however, west of Spencer Gulf and in the Lower Murray and South Coast received more than 6in. above average —Tailem Bend 893 points in excess. On the Mount Lofty Ranges also there were several heavy departures from normal, the total of 3,986 points at Mount Barker being 1,437 points above, while Uraidla, with 4,821 points, showed a surplus of 1,224 points.

Apart from the Upper Murray, where the total rain was practically the same as last year, all districts showed an improvement on the 1931 rainfall, the increase ranging from 1in. to 3in.

The following table gives the total rain at representative stations during the seven months (April to October) compared with 1931, and the average.

Total Rain, April to October—100 *Points* = 1*in.*

KYBYBOLITE FARMERS' DAY.

All previous attendances at the annual Farmers' Field Day at the Kybybolite Experimental Farm were eclipsed at the 1932 gathering held on November 9th, when over 400 people, including delegates from most of the Branches of the Agricultural Bureaux in the South-East, and visitors including several car loads from across the border under the guidance of the Manager (Mr. L. J. Cook), inspected the various experimental plots and livestock. Lecturettes were given by Messrs. L. J. Cook, R. C. Scott, H. B. Barlow, O. H. Gepp, and H. C. Trumble. Messrs. S. Shepherd and P. J. Baily attended on behalf of the Advisory Board of Agriculture. After luncheon Hon. S. R. Whitford, M.L.C. (Minister of Agriculture), and Professor A. J. Perkins (Director) addressed the gathering, and life membership certificates of the Agricultural Bureau were presented to Messrs. C. O. Hahn and E. Schinckel by the Minister. The following resolutions were carried.—"That the Department of Agriculture be requested to arrange for an interchange of judges in Crop Competitions." "That a resident veterinary surgeon be stationed in the South-East."

It was also decided that a Conference be held in each of the northern and southern ends of the South-East and that the next Conference for the lower division would be held at Penola, with the arrangements in the hands of the Penola Women's Branch. Mr. W. H. Downes (District Dairy Instructor) addressed the special session which was held for women on "Butter Making on the Farm," and Mrs. Kidman (Penola) gave a demonstration of the uses of citrus fruits.

SEED WHEAT FROM COMPETITIONS.

In Wheat Crop Competitions conducted in the undermentioned districts, the following competitors exhibited crops which, in the opinion of the judges, will produce grain suitable for seed purposes:—

District. Competitor. Address. Variety.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)

F. COLEMAN, J.P. A. E. V. RICHARDSON, M.A., D.SC.

L. T. COWAN, B.SC. PROF. A. J. PERKINS

D. A. LYALL, ESQ. W. J. ADEY, ESQ.

H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,
Agricultural College,
ROSEWORTHY.

RESULTS OF WHEAT CROP COMPETITIONS.

SEASON, 1932-33.

WESTERN DISTRICT.

PAPERS READ AT CONFERENCES.

SOME OBSERVATIONS WITH REGARD TO THE CULTIVATION OF THE NON-IRRIGATED ORCHARD.

Paper read by Mr H. N. Wicks, Balhannah (Chairman Advisory Board of Agriculture), at the Conference of Non-Irrigated Branches, held at Tanunda on Tuesday, November 1st, 1932.

The cultivation of orchard lands in localities where irrigation is impracticable is one of the most important operations of the year, for not only is the quality of the fruit dependent upon the conservation of moisture by cultivation, but the actual yield in bushels can in a measure be controlled by systematic cultivation.

Treatment of Washaways.

In comparatively steep and undulating country the matter of washaways is one which causes some orchardists much concern, and is certainly a difficult problem in some soils, especially when the slope is facing the west. In the majority of cases the most economical method of control in this connection is by heavy manuring to induce an abundance of weed growth, the ideal being the growing of a cover crop of peas or beans throughout the winter months, the latter being the most suitable for the colder districts. Washing of a serious nature is generally caused by an accumulation of very small trickles and rivulets which, in undulating country may run diagonally across a slope, being led by furrows or cultivator marks until they converge in some depression when the quantity becomes too great to be held up by the small indentations and they break through and take the shortest course to the foot of the slope. If the ploughing of a slope which is subject to washing be undertaken up and down the slope, throwing on to every row of trees and leaving a slight depression caused by finishing every land in the centre, the danger of big washaways will be minimised, owing to the fact that each land takes its own complement of water. Although small washes may occur, there will not be any excessively large cuts such as occur by the accumulation mentioned earlier. If ploughing in this way is resorted to every third or fourth season, it will be quite safe to cross-plough by the usual method of off one row and on the next for a season or two before the depressions become flattened out sufficiently to permit convergence of the small trickles from row to row. It will be found that if the usual method is to plough up and down, using the off and on method, it will take several years before the necessity for ploughing away from the centres again becomes apparent.

Cover crops offer some difficulty sometimes in getting them under, and if the weather becomes suddenly very dry the cover crop will pull so much moisture from the soil if not turned under promptly, as to make it a menace rather than a benefit. Get the cover crop in as early as possible, and as the prevention of washing is the chief aim in growing this crop, in this instance plough it under on the wet side rather than take a risk of the ground becoming too dry. Providing that a good mat of growth has resulted from the cover crop it will be found that even if turned under very early in spring and the ploughing is followed by heavy rains, washing will be negligible owing to the fact that the straw and rotting material from the crop will hold the soil. If this method is adopted the ground should not be harrowed immediately but left rough and cultivated later in the spring. Where it is impossible to prevent the collection of these small trickles, and in spite of preventive measures there are one or two lands which persistently collect enough surplus water to cause serious washing, the best plan is to leave such lands unploughed and get a covering of grass on them. If possible keep such washouts in one or two rows and leave them entirely alone so far as cultivation is concerned. If a good mat of grass can be induced on the surface, washing will be negligible, and such lands can be looked upon as permanent drains and treated as such.

THE VALUE OF THE TRACTOR IN THE ORCHARD.

The matter of implements is one which must be decided by the individual orchardist. Soil conditions will be the deciding factor in selecting the most suitable tools for this particular locality, but one implement worthy of special mention is the small tractor. It has been the firm belief of many people that only very large holdings can afford to utilise a tractor in an economical manner. This is a fallacy, in fact if it is a matter of cost of upkeep and maintenance—and these are, of course, the chief factors—then it is very often the large holding which will find the tractor the dearest method of working the land.

On a large holding with ample scope to grow plenty of fodder and plenty of paddocking room, the keeping of a team or two of horses all the year round is not a very serious or costly problem, but on the small holding with little or no paddocking this becomes a big problem both in fodder and in time. As an example, take an orchard of 20 acres which is capable of carrying a crop of 10,000 cases of fruit under ideal conditions. The value of this crop at the low figure of 2s. 6d. per case is well over £1,000. Let it be surmised that thrips are not troublesome and a perfect setting of fruit has eventuated. The land has been ploughed and harrowed into a fairly good condition with horses, and just at the critical juncture when the fruit needs it most, a deluge in the form of a thunder storm which supplies plenty of moisture is received. At the same time, however, it packs down the soil tightly. If this storm is followed by a heat wave of normal severity it will take more than two teams of horses to catch the soil before it loses the benefits of the extra irrigation. The soil is worse than before the storm in much less than a week.

It is not taking an extreme case when it is considered that by omitting to utilise this irrigation and keeping the land fit it is possible to reduce the value of the crop by at least one-third. In fact, apples in our district, which has over a 30in. rainfall, have

With a Metters about."*

become worthless from no other reason than this, and in some cases whole crops became unsaleable through being undersized. Assuming there is a crop valued at £1,250 at stake, and there is lost through inability to cultivate at the critical juncture one-third of the crop, in that season one will have lost outright two tractors. Offset against this, of course, one has the cost of the cultivation in question and the depreciation of the machine. As to cost of the work—cultivation being the matter in question—one can summarise the position thus: 1 acre per hour, 1gall. of kerosene per hour, for 20 hours and the job is done, and this is the main factor—the time in which the work can be completed. Headlamps can be fitted and the job run through without stopping for anything more than a few minutes for meals, and even these stops can be avoided if one or more drivers are available. I have in this way cultivated a 50-acre orchard in about 36 hours, during which time the tractor did not stop except for refuelling. It is this point which makes the tractor so valuable when an important crop is at stake, and so often the small orchard loses heavily owing to the slowness of horse cultivation.

Reverting to the matter of ploughing, whether done by tractor or horses, this must be completed before the soil becomes too hard, and in the non-irrigated areas there is no choice but to get at the job during the months of September and October. Just at this critical period the blossom buds are opening, the young fruit is being formed, and the tree needs all the vigor and food it is possible to collect for the immense task of setting the crop. If one examines the freshly turned soil from an orchard plough—which presumably will be ploughing in the vicinity of 4in. to 5in.—the amount of feeding roots which are turned up and broken from the tree is colossal. Just what effect on the actual setting of fruit this severance of the feeding elements of the tree has, it is hard to conjecture. Dr. Davidson, together with Mr. Evans, who are frequently in my orchard in connection with the thrips investigation, happened to come along one afternoon when a block of Jonathans—in the pink stage of blooming and showing for a wonderful crop—were being ploughed. A close examination of the soil was made, and the number of very fine hair roots visible was immense. On being asked what effect on the setting such a severance would have, Dr. Davidson's reply was that he could only surmise as to what the result might be, and thought the suggestion that a certain amount of experimenting might be valuable. Accordingly the block was left and will not be ploughed until the setting is finished. Investigation into this should not be a difficult problem.

Theoretically it would seem that to injure a tree hastens and accelerates its fruit bearing capacity and it seems to be a rule in Nature that when injured, trees and plants tend to reproduce themselves by the formation of seeds. On the other hand injury at this critical period when the tree is already exerting every effort to crop might have the reverse effect. Growers are so far in the dark in connection with this that some simple experiments should be undertaken.

CULTIVATION.

The popular belief is that if an orchard is not cultivated or neglected the root system comes nearer to the surface and the trees are much more subject to the vagaries of the weather. My experience in this connection is the opposite. The uncultivated trees often stand droughty conditions better than the cultivated ones, and as for the root systems coming to the surface, I feel sure that this is wrong; in fact reason points the other way. When ploughing to a normal depth in an orchard in early spring two things happen—the soil is warmed through aeration, and a quantity of humus, rotted leaves, and vegetation is turned under and mixed with the soil. Any manure which has been applied is contained in this top layer of warmed and finely tilled soil, and as a tree will make an enormous amount of root in a few weeks and is naturally looking for plant food, it would seem only reasonable to surmise that the root systems would revel in the ideal conditions offered them on the surface. On the other hand, the uncultivated orchard becomes packed and hard to a depth of several inches, and does not offer inducement for rapid root action owing to its earlier drying out in the spring, consequently the roots follow the moist and more congenial conditions lower down.

In some parts of the world present orchard practice is being sharply divided into two channels of thought with regard to this matter—the cultivated against the uncultivated or sod orchard as it is called. In the latter the only work done is to clip the grass for hay once or twice a year, and some of the yields from some of these orchards will equal anything put up by the cultivated ones. Were it not for the imminent and great danger of fire I would certainly try a block of trees this way, but in stringy bark country such as exists at Balhannah it matters not how many fire-breaks one may have, a spark may drift through the air for a mile or more, drop in the middle of a plot, and start a fire before anyone is aware of the danger. This would seem to preclude the practice from our particular district, but there are districts, no doubt, where orchardists would feel safe in trying out a plot under these conditions.

During the excessively dry season mentioned previously in this paper, it was very noticeable that trees which had not been cultivated for many years seemed to be less affected and certainly brought their fruit up better than trees which had been ploughed systematically for years and which were caught by the dry spell before the necessary cultivation was completed. Where the sod orchard would be safe from fires and could be brought to carry good crops it, of course, would be very profitable owing to the cheapened production costs, and such orchards would be more drought resistant than the cultivated ones in certain areas of assured rainfall.

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR DECEMBER.

[By CHAS H. BEAUMONT, District Horticultural Instructor.]

Harvesting soft fruits will be one of the main works of the month, and I must repeat what I have often said—keep the very ripe fruit for drying; keep the harder fruit in separate cases from that which is forward. The softer fruits should go in half cases. The best peaches should be packed in trays and be wrapped. A pamphlet is available for those who do not know how to go about drying.

Curculio beetle is getting troublesome again, and may be controlled with arsenate of lead—1lb. in 8galls. of water, sprayed where noticed.

Codlin moth must be kept in control, and the same old mixture gives the best results. Early apples should not be sprayed. White oils may be used later on with good results, but only use on dull days.

Root borers may be noticed on the foliage and may be picked off, or a spray as for curculio used. Cut worms can be stopped by the same treatment.

Lime sulphur may be used on dull days to clear the fusicladium, and it also lessens red spider. One gallon in 80galls. of water is the strongest that should be used.

Pear or cherry slug may be stopped by the same mixture as for codlin moth; it may be found on quite a number of shrubs other than fruit trees.

Strawberries may need irrigation and mulching.

Irrigate any trees, especially young trees, if any sign of wilting is noticed. Rub off all shoots not wanted, and keep soil loose and free from weeds.

Open up tomato houses and keep soil just moist through the day, but close up again at night.

Vines should be watched for oidium; sulphur dust is the remedy.

Keep the different varieties of almonds separate when gathering; sizing will also add to the value in the market.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

NON-IRRIGATED FRUITGROWERS' BRANCHES CONFERENCE.

The Fifth Annual Conference of Branches of the Agricultural Bureau representing the Non-Irrigated Fruitgrowing Districts of the State, was held under the auspices of the Lone Pine Branch at Tanunda on November 1st. A good attendance of delegates was present from the Balhannah, Lone Pine, Light's Pass, Cherry Gardens, Penwortham, Greenock, Lyndoch, Angaston, and Blackwood Branches. Messrs. H. N. Wicks (Chairman Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), G. Quinn (Chief Horticultural Instructor), H. B. Barlow (Chief Dairy Instructor), C. McKenna, B.V.Sc., M.R.C.V.S. (Government Veterinary Officer), H. C. Pritchard (General Secretary, Agricultural Bureau), District Horticultural Instructors, and Dr. J. Davidson, D.Sc., F.E.S., and Mr. G. Samuel, M.Sc., of the Waite Research Institute, also attended.

Mr. H. N. Wicks delivered the opening address. The following papers were read and discussed:—"Frost Damage and a Scheme for Organising Combative Measures," K. Robinson (Angaston); "Some Observations on the Cultivation of a Non-Irrigated

Orchard,'' H. N. Wicks (Balhannah); ''Currant Growing in the Clare District,'' W. H. Penna (Penwortham). Conference carried the following resolutions:—''That this Conference deputes a delegate to convene a meeting of representatives of Barossa Valley Bureaux to form an executive to formulate a frost combating organisation.'' Mr. K. Robinson was appointed to convene the meeting. ''That cultivation tests be carried out at Blackwood Orchard to determine the effect of deep cultivation (4in. or 5in.) amongst apple and stone fruits at the time of blossoming.'' ''That a field day be arranged with Messrs. J. B. Harris and G. Samuel and the Branches in the Barossa District to inspect and take specimens of apricot trees affected with gumosis.'' ''That the Department of Agriculture be asked to convene a meeting of potato growers to discuss the certification of potato seed.'' ''That this Conference approach the Royal Agricultural and Horticultural Society with a request that the schedule of points in connection with the District Agricultural Bureau Exhibit at the Royal Show be reviewed to enable the Non-Irrigated Areas more scope for their chief products.'' At present 500 points are allotted for cereals and dry farm produce which cannot be produced in a number of non-irrigated districts. Fruit and fruit products are increasing in value to State and Commonwealth. ''That the place of the 1933 Conference should be decided upon by the Advisory Board.'' ''That the sizing gauge for export apples should be standardised and officially tested.'' ''As extensive research work has now proved that the polysulphides in lime sulphur sprays alone possess fungicidal and insecticidal values the Department of Agriculture be asked to have analyses made of the various brands of lime sulphur at present on the market, and that the polysulphide contents of such samples be published in the *Journal of Agriculture*, as is now done with arsenate of lead.''

Officers of the Department of Agriculture and Waite Agricultural Research Institute replied to numerous questions, and Conference concluded with an address ''Manuring in Relation to Fruit Trees and Vines,'' by Mr. G. Quinn (Chief Horticultural Instructor).

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on November 30th, there being present:—Messrs. H. N. Wicks (Chairman), A. J. Cooke (Vice-Chairman), R. H. Martin, S. Shepherd, A. M. Dawkins, F. Coleman, G. Jeffrey, J. W. Sandford, A. L. McEwin, Prof. Perkins (Director of Agriculture), and H. C. Pritchard (Secretary). Apologies were received from Messrs. P. J. Baily and J. B. Murdoch.

Debt Adjustment.—On November 8th the Premier requested that a member of the Board be nominated for appointment to a committee to make a thorough investigation into the question of the adjustment of debts. The Chairman recommended that Mr. A. L. McEwin be appointed, and the recommendation was indorsed by the Board.

Non-Irrigated Fruitgrowers' Conference—Frost Control.—"That this Conference deputes a delegate to convene a meeting of representatives of Barossa Valley Bureaux to form an executive to formulate a frost combating organisation, and that Mr. K. Robinson be appointed to convene the meeting." Received.

Gummosis in Apricot Trees.—"That a field day be arranged with Messrs. J. B. Harris and G. Samuel and the Branches in the Barossa district to inspect and take specimens of apricot trees affected with gummosis." The Secretary reported that Messrs. Samuel and Harris were making arrangements to give effect to this resolution.

Place of Next Conference.—"That the place of the 1933 Conference should be decided upon by the Advisory Board." The Board decided to re-consider this resolution in April, 1933.

Agricultural Bureau Badge.—The Gladstone Women's Branch suggested that a badge for members of the Agricultural Bureaux might be procured. In order to obtain a representative opinion on this matter, the Board thought it advisable to bring the suggestion before the 1933 Annual Congress.

Branch Membership.—The Hanson Branch reported that a lady owner of stud cattle and Mid York pigs was desirous of becoming a member of the Branch. As there is no Women's Branch at Hanson the Branch asked for a ruling on the question of admitting ladies to membership of Men's Branches. It was decided to inform the Secretary of the Hanson Branch that on the recommendation of the Branch the lady would be admitted as a member failing the formation of a Women's Branch at Hanson.

Procedure at Annual Congress.—The Butler Branch submitted the following resolution:—"That the procedure of the Annual Congress be altered, the Free Parliament session to be extended and to take precedence of all papers." It was resolved to bring this resolution under the notice of the committee appointed to make arrangements for the 1933 Congress.

LIFE MEMBERS.—The names of Messrs. J. and G. Howard were added to the roll of life members of the Agricultural Bureau.

NEW BRANCHES.—Approval was given for the formation of new Branches at Coonawarra (Women's) and Rendelsham (Women's) with the following ladies as foundation members:—*Coonawarra*—Mesdames M. Redman, E. G. Alder, W. L. Redman, R. C. Lear, Misses O. Lear, J. Webber, R. Hinton, M. Reschke, G. Alder, E. Skinner, Mesdames J. Skinner, C. Teichelman, T. Worthington, R. Redman, E. Gaffney, J. Hinton, A. Reschke, W. Hoffman, A. Webber, O. M. Skinner, J. Kain, R. Modistach, D. Redman. *Rendelsham*—Mesdames S. Smith, F. Todd, sen., F. Todd, jun., W. Bignell, W. Inns, H. T. Sly, J. O'Toole, W. Andrews, F. R. White, Misses H. Sly, A. White, B. White.

Conditional approval was also granted for Branches at Karte and Mitcham.

NEW MEMBERS.—The following names were added to the rolls of existing Branches.—Warcowie—V. L. Sanders, R. F. Woodman, A. R. Bairstow; Jervois—L. Simms; Taragoro—M. Hamlyn; Mount Gambier—C. B. Mitchell; Greenock—A. Heinze; Millicent Women's—Mrs. J. A. Schulz; Belalie Women's—Mrs. Watkie, Mrs. D. Brookes, Sister McNeale; Penola Women's—Mrs. E. W. Stark, Mrs. McCalman; Kongorong—G. Lightbody; Waddikee Rocks—A. Moxon; Black Rock—J. Gearen, M. McMahon; Millicent—L. Watson; Wasleys Women's—Miss K. Skurray, Miss Allen, Mrs. F. Heading, Miss Joyce Heading; Goode—C. Lutze; Mangalo Women's—Mrs. H. S. Burton, Miss H. Hannemann; Parilla Women's—Miss E. Heinecke, Mrs. S. Palmer; Saddleworth Women's—Mrs. A. J. Marrett, Mrs. W. Ashton, Mrs. H. Huppatz; Mount Gambier—G. H. Dodgson; Narrung—S. Scott, H. A. Green, H. Bray, E. Dabinett; Roseworthy—John Eden, L. Heinjus, W. Shanahan; Mount Compass—A. M. Gregory; Balumbah Women's—Mrs. H. L. Van Heythusen, Mrs. R. C. Counsel, Mrs. A. Whitford; Frayville—Laurie Watchel, N. Watchel, S. A. Watchel, V. H. Dohnt, W. R. Pese, R. W. Lindner; Milang—R. J. Newland; Narrung—G. G. Hackett, J. A. Rohrlach, J. Thompson, G. Pfeiffer, H. Calf; Belvidere—Master Jim Collett; Mudamuckla—H. G. Dupree; Greenock—H. Atze, E. Atze, A. Krause; Wepowie—E. W. E. Paech, H. G. Scriven; Jamestown—R. B. Phillips; Myponga—J. R. Rowley, L. Kelsh, W. White, T. Grayham, W. A. Rowley; Wasleys Women's—Mrs. R. Evans; Roberts and Verran—R. D. Jonas; Hope Forest—John Inkster, Wm. McGee, D. Searle, A. Eves, D. Eves, M. Eves, G. Fisher, K. Bevan, S. Coad; Taragoro—J. Shaw; Goode—P. Box.

No. of new members, 80; No. of present members, 8,156; No. of Branches, 320.

Several items were dealt with in committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on December 1st, 1932:—

BUTTER.—The supplies throughout November kept up well for this period of the year, and with the warmer weather experienced at the latter end, there was a distinct falling away in production. The hot spells also affected the quality of many consignments of cream and butter. Unfortunately, the London market throughout November was very depressed, and record low levels in prices were ruling. There has, however, since been a slight improvement, which is welcome after the long spell of dropping values. Choicest creamery fresh butter, in bulk, 1s. 0¼d.; prints and delivery extra (these prices are subject to the stabilisation levies); store and collectors', 6½d. to 7d. per lb. at store door, less usual selling charges.

EGGS.—The supplies of eggs are now decreasing somewhat, but this was only to be expected with the passing of the season and hot summer conditions setting in. There is a good local demand at present for selected fresh eggs, and some export is still being done, but, unfortunately, the quality of most consignments recently has been affected by the hot weather, and values eased. Ordinary country eggs, hen or duck, 4½d. per dozen; selected, tested, and infertile, higher.

CHEESE.—Record quantities of cheese are still being manufactured by the South-Eastern factories, as the feed conditions are still good, and the market supplies to the factories are keeping up better than in the northern parts of the State. Shipments are going forward each week to Britain, and the local and Western Australian trade continues up to average. New makes, large to loaf, 6½d. to 7d.; semi-matured and matured, 9d. to 11d. per lb.

Bacon.—The demand for bacon kept up well for this period of the year, and the turnover, generally speaking, was ahead of the corresponding period last year. An improved demand also for bacon factory small goods and hams was experienced, and the factories therefore have been kept busy coping with the demand. Turnover in Christmas hams has also shown an improvement on the turnover for several years past. Best local sides, 8½d. to 9d.; best local factory-cured middles, 8½d. to 9d.; large, 8d.; local rolls, 8½d. to 9d.; local hams (raw), 1s. to 1s. 1d. ; cooked, 1s. 2d. to 1s. 3d.; lard, prints, 6d. per lb.

Almonds.—Moderate supplies came forward each week from growers, and at times there were insufficient consignments to meet all demands. However, as buyers have now purchased sufficient for their Christmas requirements, demand is not quite so brisk, although there is a fairly steady sale for good quality lots. Brandis and softshells, 10d. to 10½d.; hardshells, 6d. to 6½d.; kernels, 2s. 2d. to 2s. 3d. per lb.

Honey.—Sales are only moderate for this commodity, and except for prime quality clear extracted, there is very little other call. Prime clear extracted, in liquid condition, 3d. to 3½d.; second grade, 2d. to 2½d. per lb.

Beeswax came forward in better quantities throughout November and sold readily, 1s. 0½d. to 1s. 1d. per lb., according to sample.

Live Poultry.—The demand for live poultry was well maintained throughout November, and supplies show considerable increase. A large proportion of the catalogue submitted, however, was only of the lighter breeds and old hens, and for these values eased somewhat. With buyers operating strongly for Christmas poultry, however, any lots of prime quality heavy weight young birds sold readily at satisfactory prices, and we anticipate that this demand will continue, but would strongly advise consignors to market their birds straight away rather than leave till closer up to the festive season. Prime roosters, 4s. to 5s.; nice conditioned cockerels, 2s. 9d. to 3s. 9d.; fair conditioned cockerels, 2s. to 2s. 8d.; chickens, lower; heavy weight hens, 2s. 9d. to 3s. 9d.; medium hens, 2s. to 2s. 7d.; light hens, 1s. 4d. to 1s. 9d.; couple of pens of weedy sorts lower; geese, 4s. to 6s.; goslings, lower; prime young Muscovy drakes, 4s. to 5s. 3d.; young Muscovy ducks, 2s. 3d. to 3s.; ordinary ducks, 1s. to 2s.; ducklings, lower; turkeys, good to prime condition, 8½d. to 10½d. per lb. live weight; turkeys, fair condition, 6½d. to 8d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 4d. to 6d. each.

Potatoes.—Old season's, 4s. 6d. per cwt.; W.A., new, 8s.; local, new, 8s. per cwt.

Onions.—New season's, 7s. per cwt.
